Part I.

General
1. Introduction

Introduction

Essentially, this document is divided into three parts. In the BICsuite Scheduling System, there are three types of users (in the broadest sense of the word):

- Users
- Job servers
- Jobs

Each of these users has his own command set at his disposal. These command sets only overlap to a certain extent. For example, for job servers there is the statement `get next job`, which is not valid for either jobs or users. On the other hand, there are forms of the `submit` statement will only make sense in a job context and which can therefore only be implemented by jobs. Obviously only users are allowed to create objects such as Exit State definitions or job definitions. In contrast, there are also statements such as the `connect` statement which is valid for all types of users.

The structure of this document is oriented to the three types of users. The largest part of this document deals with the user commands, while the two other parts handle job servers and job commands.

For the sake of completeness, the next chapter briefly explains the utility `sdmsh`. This utility is easy to use and is an excellent choice for processing scripts using BICsuite commands.

Since the syntax described here is the only interface to the BICsuite Scheduling Server, all the utilities (and in particular BICsuite!Web) use this web interface. To simplify the development of proprietary utilities, the server is capable of returning its reactions to statements in various formats. The utility `sdmsh`, for example, uses the `serial` protocol, with which serialised Java objects are transferred. In contrast BICsuite!Web uses the `python` protocol, with which textual representations of Python structures are transferred that can be easily read in using the eval() function.

Syntax diagrams

The syntax diagrams are comprised of different symbols and metasymbols. The symbols and metasymbols are listed and explained in the table below.
Symbol | Meaning
--- | ---
**keyword** | A keyword in the language. These have to be entered as shown. One example is the keyword **create**.

**name** | A parameter. In many cases, the user can choose a name or a number to be entered here.

**NONTERM** | A non-terminal symbol is represented by small caps. A syntax element that is explained further on in the diagram has to be inserted here.

< **all** | any > | This syntax element is an optional choice. One of the syntax elements given in the angle brackets, which can obviously also be non-terminal symbols, has to be selected. In the simplest scenario there are only two choices that can be made here, although frequently there are more.

< **all** | any > | This is also an optional choice. Unlike the previous syntax element, the underscore of the first element emphasises that this option is the default choice.

[ **or alter** ] | Optional syntax elements are placed in square brackets.

{ **statename** } | Syntax elements that are placed in braces are repeated 0 to n times.

**JOB_PARAMETER** | Cases where elements occur at least once are far more common and are shown as represented here.

{, **JOB_PARAMETER**} | In lists of possible syntax elements, the single possibilities are separated by a |. Such a list is another way of displaying optional choices. These two different forms of presentation are used for purposes of clarity.

**Literals**

**Literals** | Literals are only required in the language definition for strings, numbers, and dates/times.

Strings are delimited by single quotes, as in

```
node = 'puma.independit.de'
```

Integers are shown as either unsigned **integer** or signed **signed_integer** in the syntax diagrams. A **signed_integer** can be prefixed with a + or - sign. Valid unsigned integers lie in the range of numbers between 0 and $2^{31} - 1$. Signed integers are therefore within the range between $-2^{31} + 1$ and $2^{31} - 1$. If the syntax diagram contains **id**, an unsigned integer between 0 and $2^{63} - 1$ is expected here.
Much more complicated are dates/times, particularly in statements concerning the time scheduling. These literals are principally shown as strings with a special format. The following syntax is used to comply with the notations based on ISO8601 as given in Table 1.1:

<table>
<thead>
<tr>
<th>String</th>
<th>Meaning</th>
<th>Range</th>
<th>String</th>
<th>Meaning</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>YYYY</td>
<td>year</td>
<td>1970 .. 9999</td>
<td>hh</td>
<td>hour</td>
<td>00 .. 23</td>
</tr>
<tr>
<td>MM</td>
<td>month</td>
<td>01 .. 12</td>
<td>mm</td>
<td>minute</td>
<td>00 .. 59</td>
</tr>
<tr>
<td>DD</td>
<td>day (of the month)</td>
<td>01 .. 31</td>
<td>ss</td>
<td>second</td>
<td>00 .. 59</td>
</tr>
<tr>
<td>ww</td>
<td>week (of the year)</td>
<td>01 .. 53</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- All other strings stand by themselves.
- No differentiation is made between uppercase and lowercase.
- The earliest permissible point in time is 1970–01-01T00:00:00 GMT.

**Identifier**

In the BICsuite Scheduling System, objects are identified by their names. (Strictly speaking, objects can also be identified from their internal ID, which is a number, but this practice is not recommended). Valid names comprise a letter, underscore (_), at sign (@) or hash sign (#) followed by numbers, letters or special characters. Language-specific special characters such as the German umlaut are invalid. Identifiers are treated as being case-insensitive if they are not enclosed in simple quotes. Identifiers enclosed in quotes are case-sensitive. It is therefore not generally recommended to use quotes unless there is a valid reason for doing so. Identifiers that are allowed to be enclosed in single quotes can also contain spaces and several special characters. Again, this practice is not recommended as spaces are normally interpreted as delimiters and therefore errors can easily occur. Spaces aren’t allowed at the beginning or end of an identifier.

There are a number of keywords in the syntax that cannot be readily used as identifiers. Here it may be practicable to use quotes so that the identifiers are not recognised as keywords. Table 1.2 contains a list of such keywords.

There are also a number of synonyms. These are essentially keywords that can be written in more than one way. Only one spelling variation is shown in Table 1.2. The synonyms can be used together arbitrarily. Table 1.3 gives a list of such synonyms.

</tbody>
</table>

Table 1.1.: Valid date formats:

As in any language, there are also some reserved words and word combinations. An overview is shown in Table 1.4. A special characteristic of word pairs is that replacing a space with an underscore likewise produces a reserved word. The word named_resource is therefore reserved (but “named#resource” isn’t).

### Versions

There are three versions of the BICsuite Scheduling System. Since features from later versions are not always present in the earlier versions, the relevant statements or options within the statements are designated accordingly. A letter in the top cor-
The page indicates for which version of the system this statement is available. Deviations from the general statement are shown in the syntax diagram. The symbols have the following meanings:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>This symbol indicates a feature in the Basic version and all later versions.</td>
</tr>
<tr>
<td>P</td>
<td>This symbol indicates a feature in the Professional and Enterprise versions and all later versions.</td>
</tr>
<tr>
<td>E</td>
<td>This symbol indicates a feature in the Enterprise version.</td>
</tr>
</tbody>
</table>

Table 1.4.: Reserved words
2. Utilities

Starting and stopping the server

server-start

Introduction

The utility server-start is used to start the scheduling server.

Call

The following commands are used to call server-start:

server-start [ OPTIONS | config-file ]

OPTIONS:

- admin
- protected

The individual options have the following meanings:

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>- admin</td>
<td>The server starts in Admin mode. This means that user logins are disabled apart from the user SYSTEM.</td>
</tr>
<tr>
<td>- protected</td>
<td>Protected mode is similar to Admin mode. The difference here is that the internal threads (TimerThread and SchedulingThread) are not started. This allows administrative tasks to be carried out without concurrent transactions being performed.</td>
</tr>
</tbody>
</table>

If the server has already been started, the second server either (depending on the configuration) takes over the operation or repeatedly makes an unsuccessful attempt to start.

The server-start utility can be only be used by the user whose ID was used to install the system.
**server-stop**

**Introduction**

The `server-stop` utility is used to stop the scheduling server.

**Call**

The following command is used to call server-stop:

```
server-stop
```

Initially, an attempt is made to stop the server 'gracefully'. First, all the user connections are terminated to stop all the internal threads. If this approach fails or it takes too long, the server is stopped using the operating system’s mechanisms. If the server has not been started, the server-stop command has no effect. The server-stop utility can be only be used by the user whose ID was used to install the system.

**sdmsh**

**Introduction**

The `sdmsh` utility is a small program that enables the user to interactively work with the scheduling server. In contrast to the BICsuite!Web front end, for instance, this working method is text-oriented. This means it is possible to write scripts and execute them using `sdmsh`. The `sdmsh` executable is a small script or batch file that encapsulates the call of the required Java program. Of course, there is no reason why this Java program should not be called manually. It is only there for convenience’s sake.

**Call**

The following commands are used to call sdmsh:

```
sdmsh [ OPTIONS ] [ username [ password [ host [ port ] ] ] ]
```

OPTIONS:

- `<--host | -h > hostname`
- `<--port | -p > portnumber`
- `<--user | -u > username`
- `<--pass | -w > password`
- `<--jid | -j > jobid`
The individual options have the following meanings:

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; --host</td>
<td>-h &gt; hostname</td>
</tr>
<tr>
<td>&lt; --port</td>
<td>-p &gt; portnumber</td>
</tr>
<tr>
<td>&lt; --user</td>
<td>-u &gt; username</td>
</tr>
<tr>
<td>&lt; --pass</td>
<td>-w &gt; password</td>
</tr>
<tr>
<td>&lt; --jid</td>
<td>-j &gt; jobid</td>
</tr>
<tr>
<td>&lt; --key</td>
<td>-k &gt; jobkey</td>
</tr>
<tr>
<td>&lt; --[ no ]silent</td>
<td>-[ no ]s &gt;</td>
</tr>
<tr>
<td>&lt; --[ no ]verbose</td>
<td>-[ no ]v &gt;</td>
</tr>
<tr>
<td>&lt; --ini</td>
<td>-ini &gt; inifile</td>
</tr>
<tr>
<td>&lt; --[ no ]tls</td>
<td>-[ no ]tls &gt;</td>
</tr>
<tr>
<td>--[ no ]help</td>
<td></td>
</tr>
<tr>
<td>--info sessioninfo</td>
<td></td>
</tr>
<tr>
<td>-[ no ]S</td>
<td></td>
</tr>
<tr>
<td>--timeout timeout</td>
<td></td>
</tr>
</tbody>
</table>

**sdmsh** obviously requires information to connect to the correct BICsuite Scheduling System. The necessary data can be specified in the command line or by using an options file. Missing values for the user name and password are queried by **sdmsh**. If values for the host and port are not given, the defaults values “localhost” and 2506 are used. It is not advisable to specify the password in the command line.
because this information can frequently be easily read out by other users.

**Options file**

The options file has the same format as a Java property file. Please refer to the official Java documentation for details of the precise syntax specification. The following option files play a role:

- `$SDMSCONFIG/sdmshrc`
- `$HOME/.sdmshrc`
- Optionally, a file specified in the command line

The files are evaluated in the given order. If options are present in several files, the value in the last evaluated file “wins”. Options that are specified in the command line take precedence over all the other specifications. The following keywords are recognised:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>User</td>
<td>The user’s name</td>
</tr>
<tr>
<td>Password</td>
<td>The user’s password</td>
</tr>
<tr>
<td>Host</td>
<td>Name or IP address of the host</td>
</tr>
<tr>
<td>Info</td>
<td>Additional information for identifying a connection is set</td>
</tr>
<tr>
<td>Port</td>
<td>Port number of the scheduling server (default: 2506)</td>
</tr>
<tr>
<td>Silent</td>
<td>(Error) messages are not returned</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout value for the session (0 means no timeout)</td>
</tr>
<tr>
<td>TLS</td>
<td>Use an SSL/TLS connection</td>
</tr>
<tr>
<td>Verbose</td>
<td>Commands, feedback and additional messages are returned</td>
</tr>
</tbody>
</table>

Since the user’s password is shown in plain text in this file, careful consideration needs to be taken when assigning the access privileges for this file. It is, of course, possible to not specify the password and to enter it every time `sdmsh` is started. Only the following keywords can be used in configuration files:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>KeyStore</td>
<td>Keystore for TLS/SSL communication</td>
</tr>
<tr>
<td>TrustStore</td>
<td>Truststore for TLS/SSL communication</td>
</tr>
<tr>
<td>KeyStorePassword</td>
<td>Keystore password</td>
</tr>
<tr>
<td>TrustStorePassword</td>
<td>Truststore password</td>
</tr>
</tbody>
</table>

**Internal commands**

Apart from the BICsuite commands described in the following chapters, *sdmsh* also knows a few simple commands of its own. These are briefly described below.

Internal commands do not have to be closed with a semicolon.

**disconnect**  The disconnect command is used to exit *sdmsh*. Because different commands are commonly used to exit a tool in different work environments, an attempt was made here to incorporate many varying formulations. The syntax for the disconnect command is:

```
< disconnect | bye | exit | quit >
```

**EXAMPLE** Here is an example of the disconnect command.

```
ronald@jaguarundi:~$ sdmsh
Connect

CONNECT_TIME : 23 Aug 2007 07:13:30 GMT
Connected
[system@localhost:2506] SDMS> disconnect
ronald@jaguarundi:~$
```

**echo**  If *sdmsh* is being used interactively, it is visually evident which command has just been entered. This is not the case in batch mode, i.e. when processing a script. The echo command can be used to enable and disable the rendering of the entered statement. This is enabled by default. The syntax for the echo command is:

```
echo < on | off >
```

**EXAMPLE** The effect of these two options is shown below. Following the command `echo on`

```
[system@localhost:2506] SDMS> echo on
End of Output

[system@localhost:2506] SDMS> show session;
show session;
Session

   THIS : *
SESSIONID : 1001
START : Tue Aug 23 11:47:34 GMT+01:00 2007
USER : SYSTEM
```

help  The help command opens a condensed help text about the internal \textit{sdmsh} commands. The syntax for the help command is:

\texttt{help}

\textbf{Example} The help command only returns a condensed help text about the syntax for the internal \textit{sdmsh} commands. This is shown in the example below. (The lines have been wrapped for this document and so the actual output may differ to what is written here).

\begin{verbatim}
 [system@localhost:2506] SDMS> help
 Condensed Help Feature
 Internal sdmsh Commands:
 disconnect|bye|exit|quit -- leaves the tool
echo on|off -- controls whether the statement text is printed or not
\end{verbatim}
help -- gives this output
include '<filespec>' -- reads sdms(h) commands from the given file
prompt '<somestring>' -- sets to prompt to the specified value
%H = hostname, %P = port, %U = user, %% = %
timing on|off -- controls whether the actual time is printed or not
whenever error continue|disconnect <integer> -- specifies the behaviour of the program in case of an error
!<shellcommand> -- executes the specified command. sdmsh has no intelligence at all regarding terminal I/O

End of Output

[system@localhost:2506] SDMS>

include Files can be integrated into BICsuite statements using the include command.
The syntax for the include command is:

    include 'filespec'

EXAMPLE In the following example, a file only containing the command "show session;" is inserted.

    [system@localhost:2506] SDMS> include '/tmp/show.sdms'
    Session
        THIS : *
        SESSIONID : 1001
        START : Tue Aug 23 11:47:34 GMT+01:00 2007
        USER : SYSTEM
        UID : 0
        IP : 127.0.0.1
        TXID : 136493
        IDLE : 0
        TIMEOUT : 0
        STATEMENT : show session
    Session shown

[system@localhost:2506] SDMS>

prompt The prompt command can be used to specify an arbitrary prompt. There are a number of variable values that can be inserted automatically by the program. The codes for the individual variables are shown in the table below:
The default prompt has the following definition: [%U@%H:%P] SDMS>

The syntax for the prompt command is:

```
prompt 'somestring'
```

**EXAMPLE** In the following example, an empty prompt is defined first. A BICsuite statement is then executed to make the effect more clearly visible. A simple string is then selected as a prompt, and finally the variables are used.

```
[system@localhost:2506] SDMS> prompt ''
End of Output

show session;
show session;

Session

    THIS : *
SESSIONID : 1001
START : Tue Aug 23 11:47:34 GMT+01:00 2007
USER : SYSTEM
UID : 0
IP : 127.0.0.1
TXID : 136532
IDLE : 0
TIMEOUT : 0
STATEMENT : show session

Session shown
prompt 'hello world '

End of Output

hello world prompt ' [%U@%H:%P] please enter your wish! > '

End of Output

[system@localhost:2506] please enter your wish! >
```

**timing** The timing command provides information about the execution time for a statement. Normally, this option is disabled and so no information about the
execution time is given. The time is stated in milliseconds. The syntax for the timing command is:

\texttt{timing < off | on >}

**Example** The following example shows the timing information for a simple BIC-suite statement. The execution time for the statements and the time that was required to output the result is shown.

```
[system@localhost:2506] SDMS> timing on
End of Output

[system@localhost:2506] SDMS> show session;
Execution Time: 63
show session;
```

Session

- THIS : *
- SESSIONID : 1002
- START : Tue Aug 23 11:53:15 GMT+01:00 2007
- USER : SYSTEM
- UID : 0
- IP : 127.0.0.1
- TXID : 136559
- IDLE : 0
- TIMEOUT : 0
- STATEMENT : show session

Session shown

 livestream : 0
```

whenever An error handling routine is absolutely essential particularly when \texttt{sdmsh} is being used to execute scripts. The whenever statement tells \texttt{sdmsh} how to deal with errors. By default errors are ignored, which also corresponds to the desired behaviour for interactive working. The syntax for the whenever command is:

\texttt{whenever error < continue | disconnect integer >}

**Example** The example below shows the behaviour of both the \texttt{continue} option and the \texttt{disconnect} option. The Exit Code for a process that was started by the Bourne shell (and other Unix shells as well) can be shown by outputting the variable $? .

```
[system@localhost:2506] SDMS> whenever error continue
End of Output
```

 livestream : 0
[system@localhost:2506] SDMS> show exit state definition does_not_exist;
show exit state definition does_not_exist;
ERROR:03201292040, DOES_NOT_EXIST not found
[system@localhost:2506] SDMS> whenever error disconnect 17
End of Output
[system@localhost:2506] SDMS> show exit state definition does_not_exist;
show exit state definition does_not_exist;
ERROR:03201292040, DOES_NOT_EXIST not found
[system@localhost:2506] SDMS>
ronald@jaguarundi:~$ echo $?
17
ronald@jaguarundi:~$

Shell call  It frequently happens that a shell command has to be quickly executed,
for instance to see what the file that is to be run (using include) is called. If no
special capabilities are required of the terminal, such as is the case when calling an
editor, a shell command can be executed by prefixing it with an exclamation mark.
The syntax for a shell call is:

!shellcommand

Example In the following example, a short list of all the sdmsh scripts in the /tmp
directory is outputted.

[system@localhost:2506] SDMS> !ls -l /tmp/*.sdms
-rw-r--r-- 1 ronald ronald 15 2007-08-23 09:30 /tmp/ls.sdms
End of Output
[system@localhost:2506] SDMS>

sdms-auto_restart

Introduction

The utility sdms-auto_restart is used to automatically restart jobs that have failed.
A number of simple conditions have to be met to do this. Probably the most impor-
tant condition is that the job defines a parameter AUTORESTART with the value
TRUE. This parameter can naturally also be set at a higher level.
The following parameters influence the behaviour of the autorestart utilities:
The autorestart utility can be defined as a trigger. The trigger types IMMEDIATE_LOCAL and FINISH_CHILD can be used.

The logic of the option files that applies for the sdms utility is also used for sdms-auto_restart.

Call

The following commands are used to call sdms-auto_restart:

```
sdms-auto_restart [ OPTIONS | < --host | -h > hostname
< --port | -p > portnumber < --user | -u > username
< --pass | -w > password < --failed | -f > jobid
```

OPTIONS:

```
< --silent | -s >
< --verbose | -v >
< --timeout | -t > minutes
< --cycle | -c > minutes
< --help | -h >
< --delay | -d > seconds
< --max | -m > number
< --warn | -W >
```

The individual options have the following meanings:
sdms-get_variable

Introduction

The utility sdms-get_variable offers a simple way of reading out job parameters from the scheduling system.

The logic of the option files that applies for the sdmsh utility is also used for sdms-get_variable.

Call

The following commands are used to call sdmsh-get_variable:

```
   sdms-get_variable [ OPTIONS ] < --host | -h > hostname
   < --port | -p > portnumber < --jid | -j > jobid
   < --name | -n > parametername
```

OPTIONS:

```
   < --user | -u > username
```
The individual options have the following meanings:

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; --host</td>
<td>hostname</td>
</tr>
<tr>
<td>&lt; --port</td>
<td>portnumber</td>
</tr>
<tr>
<td>&lt; --user</td>
<td>username</td>
</tr>
<tr>
<td>&lt; --pass</td>
<td>password</td>
</tr>
<tr>
<td>&lt; --key</td>
<td>jobkey</td>
</tr>
<tr>
<td>&lt; --silent</td>
<td>silent</td>
</tr>
<tr>
<td>&lt; --verbose</td>
<td>verbose</td>
</tr>
<tr>
<td>&lt; --timeout</td>
<td>timeout</td>
</tr>
<tr>
<td>&lt; --cycle</td>
<td>cycle</td>
</tr>
<tr>
<td>&lt; --help</td>
<td>help</td>
</tr>
<tr>
<td>&lt; --mode</td>
<td>mode</td>
</tr>
</tbody>
</table>

Example

The example below shows how to get the variable value of the variable RESPONSE of job 5175119.

```bash
ronald@cheetah:~$ sdms-get_variable -h localhost -p 2506 -j 5175119 -u donald -w duck -n RESPONSE
```
sdms-rerun

Introduction

The utility *sdms-rerun* is used to rerun a job in a restartable state from a script or program.

The logic of the option files that applies for the *sdmsh* utility is also used for *sdms-rerun*.

Call

The following commands are used to call *sdms-rerun*:

```
sdms-rerun [OPTIONS] < --host | -h > hostname
< --port | -p > portnumber < --jid | -j > jobid
```

OPTIONS:
- < --user | -u > username
- < --pass | -w > password
- < --key | -k > jobkey
- < --silent | -s >
- < --verbose | -v >
- < --timeout | -t > minutes
- < --cycle | -c > minutes
- < --help | -h >
- < --suspend | -S >
- < --delay | -D > delay
- < --unit | -U > unit
- < --at | -A > at

The individual options have the following meanings:
**sdms-set_state**

**Introduction**

The utility *sdms-set_state* offers a simple way of setting the state of a job in the scheduling system. The logic of the option files that applies for the sdmsh utility is also used for sdms-set_state.

**Call**

The following commands are used to call sdmsh-set_state:

```
sdms-set_state [ OPTIONS ] < --host | -h > hostname
< --port | -p > portnumber < --jid | -j > jobid
< --state | -S > statename
```

OPTIONS:

```
< --user | -u > username
```
General

```
< --pass | -w > password
< --key | -k > jobkey
< --silent | -s >
< --verbose | -v >
< --timeout | -t > minutes
< --cycle | -c > minutes
< --help | -h >
< --force | -f >
```

The individual options have the following meanings:

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; --host</td>
<td>hostname</td>
</tr>
<tr>
<td>&lt; --port</td>
<td>portnumber</td>
</tr>
<tr>
<td>&lt; --user</td>
<td>username</td>
</tr>
<tr>
<td>&lt; --pass</td>
<td>password</td>
</tr>
<tr>
<td>&lt; --key</td>
<td>jobkey</td>
</tr>
<tr>
<td>&lt; --silent</td>
<td>-s &gt;</td>
</tr>
<tr>
<td>&lt; --verbose</td>
<td>-v &gt;</td>
</tr>
<tr>
<td>&lt; --timeout</td>
<td>-t &gt; minutes</td>
</tr>
<tr>
<td>&lt; --cycle</td>
<td>-c &gt; minutes</td>
</tr>
<tr>
<td>&lt; --help</td>
<td>-h &gt;</td>
</tr>
<tr>
<td>&lt; --force</td>
<td>-f &gt;</td>
</tr>
</tbody>
</table>

**sdms-set_variable**

**Introduction**

The utility `sdms-set_variable` offers a simple way of setting job parameters in the scheduling system. The logic of the option files that applies for the sdmsh utility is also used for `sdms-set_variable`. 
The following commands are used to call `sdms-set_variable`:

```
sdms-set_variable [OPTIONS] | < --host | -h > hostname
| < --port | -p > portnumber < --jid | -j > jobid
| parametername value { parametername value}
```

**OPTIONS:**
- `< --user | -u > username`
- `< --pass | -w > password`
- `< --key | -k > jobkey`
- `< --silent | -s >`
- `< --verbose | -v >`
- `< --timeout | -t > minutes`
- `< --cycle | -c > minutes`
- `< --help | -h >`
- `< --case | -C >`

The individual options have the following meanings:

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>`&lt; --host</td>
<td>-h &gt; hostname`</td>
</tr>
<tr>
<td>`&lt; --port</td>
<td>-p &gt; portnumber`</td>
</tr>
<tr>
<td>`&lt; --user</td>
<td>-u &gt; username`</td>
</tr>
<tr>
<td>`&lt; --pass</td>
<td>-w &gt; password`</td>
</tr>
<tr>
<td>`&lt; --key</td>
<td>-k &gt; jobkey`</td>
</tr>
<tr>
<td>`&lt; --silent</td>
<td>-s &gt;`</td>
</tr>
<tr>
<td>`&lt; --verbose</td>
<td>-v &gt;`</td>
</tr>
<tr>
<td>`&lt; --timeout</td>
<td>-t &gt; minutes`</td>
</tr>
<tr>
<td>`&lt; --cycle</td>
<td>-c &gt; minutes`</td>
</tr>
<tr>
<td>`&lt; --help</td>
<td>-h &gt;`</td>
</tr>
<tr>
<td>`&lt; --case</td>
<td>-C &gt;`</td>
</tr>
</tbody>
</table>
sdms-set_warning

Introduction

The utility `sdms-set_warning` is used to set the warning flag for a job. A text can be optionally specified. The warning flag can be set for a job by users who have been granted the Operate privilege. A job can set the warning flag for itself.

The logic of the option files that applies for the sdmsh utility is also used for sdms-set_warning.

Call

The following commands are used to call sdms-set_warning:

```
sdms-set_warning [ OPTIONS ] < --host | -h > hostname
< --port | -p > portnumber < --jid | -j > jobid
```

OPTIONS:

```
< --user | -u > username
< --pass | -w > password
< --key | -k > jobkey
< --silent | -s >
< --verbose | -v >
< --timeout | -t > minutes
< --cycle | -c > minutes
< --help | -h >
< --warning | -m > warning
```

The individual options have the following meanings:
### sdms-submit

#### Introduction

The utility `sdms-submit` is used to start jobs or batches. These can be started as a standalone workflow or also as a child of an existing job. In the latter case, if it is defined in the parent-child hierarchy an alias can be specified to identify the job or batch that is to be submitted. The logic of the option files that applies for the `sdmsh` utility is also used for `sdms-submit`.

#### Call

The following commands are used to call `sdms-submit`:

```
  sdms-submit [OPTIONS] < --host | -h > hostname
  < --port | -p > portnumber < --job | -j > jobname
```

OPTIONS:

- `< --user | -u > username`
- `< --pass | -w > password`
- `< --jid | -j > jobid`
- `< --key | -k > jobkey`

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>`&lt; --host</td>
<td>-h &gt; hostname`</td>
</tr>
<tr>
<td>`&lt; --port</td>
<td>-p &gt; portnumber`</td>
</tr>
<tr>
<td>`&lt; --user</td>
<td>-u &gt; username`</td>
</tr>
<tr>
<td>`&lt; --pass</td>
<td>-w &gt; password`</td>
</tr>
<tr>
<td>`&lt; --key</td>
<td>-k &gt; jobkey`</td>
</tr>
<tr>
<td>`&lt; --silent</td>
<td>-s &gt;`</td>
</tr>
<tr>
<td>`&lt; --verbose</td>
<td>-v &gt;`</td>
</tr>
<tr>
<td>`&lt; --timeout</td>
<td>-t &gt; minutes`</td>

Part II.

User Commands
3. alter commands
**User Commands**

**alter comment**

**Purpose**

*Purpose* The purpose of the `alter comment` statement is to change the comment for the specified object.

**Syntax**

*Syntax* The syntax for the `alter comment` statement is

```
alter [ existing ] comment on OBJECTURL
with CC_WITHITEM

OBJECTURL:
  distribution distributionname for pool resourcepath in serverpath
  | environment environmentname
  | exit state definition statename
  | exit state mapping mappingname
  | exit state profile profilename
  | event eventname
  | resource resourcepath in folderpath
  | folder folderpath
  | footprint footprintname
  | group groupname
  | interval intervalname
  | job definition folderpath
  | job jobid
  | named resource resourcepath
  | parameter parametername of PARAM_LOC
  | resource state definition statename
  | resource state mapping mappingname
  | resource state profile profilename
  | scheduled event schedulepath . eventname
  | schedule schedulepath
  | resource resourcepath in serverpath
  | < scope serverpath | job server serverpath >
  | trigger triggername on TRIGGEROBJECT [ < noinverse | inverse > ]
  | user username

CC_WITHITEM:
  CC_TEXTITEM {, CC_TEXTITEM}
```
The alter comment command is used to change the condensed description or URL of the description of the object in question. Of course, the type of information can be changed as well. The comment is versioned. This means that comments are not overwritten. When the commented object is displayed, the displayed comment is the one that matches the version of the displayed object. The optional existing keyword is used to prevent error messages from being displayed and the current operation from being terminated. This is particularly useful in conjunction with multicommands.

Output

This statement returns a confirmation of a successful operation.
alter environment

Purpose

The purpose of the alter environment statement is to alter the properties of the specified environment.

Syntax

The syntax for the alter environment statement is

```
alter [ existing ] environment environmentname
  with ENV_WITH_ITEM

alter [ existing ] environment environmentname
  add ( ENV_RESOURCE {, ENV_RESOURCE} )

alter [ existing ] environment environmentname
  delete ( resourcepath {, resourcepath} )
```

```
ENV_WITH_ITEM:
  resource = none
  | resource = ( ENV_RESOURCE {, ENVRESOURCE} )

ENV_RESOURCE:
  resourcepath [ < condition = string | condition = none > ]
```

Description

The alter environment statement is used to change the resource requests that are defined in this environment. Running jobs are not affected. The "with resource =" form of the statement replaces the existing group of resource requests. The other types either add the specified requests or deletes them. It is considered an error to delete a request that is not part of the environment or to add a request for an already required resource. Only administrators are authorised to perform this action.

Output

This statement returns a confirmation of a successful operation
alter event

Purpose

The purpose of the alter event statement is to change properties of the specified event.

Syntax

The syntax for the alter event statement is

```plaintext
alter [existing] event eventname
with EVENT_WITHITEM {, EVENT_WITHITEM}

EVENT_WITHITEM:
  action =
    submit folderpath [with parameter = (PARAM {, PARAM}) ]
  | group = groupname

PARAM:
  parametername = <string | number>
```

Description

The alter event statement is used to change the properties of an event. A parameter for a job submit can be specified using the with parameter clause. For a detailed description of these options, refer to the create event statement on page 83.

Output

This statement returns a confirmation of a successful operation.
**alter exit state mapping**

**Purpose**

The purpose of the *alter exit state mapping* statement is to change properties of the specified mapping.

**Syntax**

The syntax for the *alter exit state mapping* statement is

```
alter [ existing ] exit state mapping mappingname
with map = ( statename , signed_integer , statename )
```

**Description**

The *alter exit state mapping* statement defines the mapping of the Exit Codes for logical Exit States. The simplest form of this statement only specifies one Exit State. This means that the job acquires this Exit State when it finishes regardless of its Exit Code. More complex definitions specify more than one Exit State and at least one delimitation.

A statement like

```
alter exit state mapping example1
with map = ( failure,
            0 , success ,
            1 , warning ,
            4 , failure );
```

defines the following mapping:

<table>
<thead>
<tr>
<th>Exit code range from</th>
<th>Exit code range until</th>
<th>Resulting exit state</th>
</tr>
</thead>
<tbody>
<tr>
<td>$-\infty$</td>
<td>-1</td>
<td>failure</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>success</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>warning</td>
</tr>
<tr>
<td>4</td>
<td>$\infty$</td>
<td>failure</td>
</tr>
</tbody>
</table>

**Output**

This statement returns a confirmation of a successful operation
alter exit state profile

Purpose

The purpose of the alter exit state profile statement is to change properties of the specified profile.

Syntax

The syntax for the alter exit state profile statement is

```
alter [existing] exit state profile profilename
with withitem {, withitem}
```

```
WITHITEM:
  default mapping = < none | mappingname >
  | force
  | state = ( ESP_STATE {, ESP_STATE} )

ESP_STATE:
  statename < final | restartable | pending > [ option { option} ]
```

```
OPTION:
  < unreachable | broken | batch default | dependency default >
```

Description

The alter exit state profile statement is used to add Exit States to the profile or delete them, as well as to define the default Exit State Mapping. For a detailed description of these options, refer to the create exit state profile statement on page 86.

force  The force option labels the Exit State Profiles as being invalid, which only means that the integrity still has to be verified. The label is removed after a successful verification. The verification is carried out by submitting a job definition that uses the Exit State Profiles. The purpose of the force flag is to be capable of changing several Exit State Profiles (and perhaps some other objects) without the need for a consistent state after each change.

Output

This statement returns a confirmation of a successful operation
User Commands

alter folder

**alter folder**

**Purpose**  
The purpose of the alter folder statement is to alter the properties of a folder.

**Syntax**  
The syntax for the alter folder statement is

```
alter [ existing ] folder folderpath  
with WITHITEM {, WITHITEM}
```

**Description**  
The alter folder statement changes the properties of a folder. For a detailed description of these options, refer to the create folder statement on page 89.

If the optional existing keyword has been specified, no error is created if the specified folder does not exist.

Although the folder SYSTEM cannot be created, dropped or renamed, it can be altered to some extend. It is not possible to change the owning group, but it is possible to specify an environment or to create parameters.
Output

This statement returns a confirmation of a successful operation
alter footprint

Purpose
The purpose of the alter footprint statement is to change the properties of the specified footprint.

Syntax
The syntax for the alter footprint statement is

```plaintext
alter [existing] footprint footprintname
with resource = ( REQUIREMENT {, REQUIREMENT} )

alter [existing] footprint footprintname
add resource = ( REQUIREMENT {, REQUIREMENT} )

alter [existing] footprint footprintname
delete resource = ( resourcepath {, resourcepath} )
```

**ITEM**: 
- `amount = integer`
- `<nokeep | keep | keep final>`
- `resourcepath`

Description
The alter footprint command changes the list of resource requests. There are three kinds of this statement:

- The first one determines all the resource requests.
- The second one adds resource requests to the request list.
- The third kind removes requests from the list.

For a detailed description of these options, refer to the create footprint statement on page 91.

Output
This statement returns a confirmation of a successful operation
**alter group**

**Purpose**

The purpose of the alter group statement is to alter the user to group assignments.

**Syntax**

The syntax for the alter group statement is

```
alter [existing] group groupname
with WITHITEM

alter [existing] group groupname
ADD_DELITEM {}, ADD_DELITEM

WITHITEM:
  user = none
  | user = ( username {}, username )

ADD_DELITEM:
  < add | delete > user = ( username {}, username )
```

**Description**

The alter group command is used to define which users belong to the group. There are two kinds of this statement:

- The first one defines the list of users who belong to the group.
- The second one adds users to the group or deletes them.

In all cases, deleting users from their default group is considered to be an error. It is not possible to delete users from the PUBLIC group. If a user does not belong to a group, any attempt made to delete the user from this group is ignored. If the `existing` keyword has been specified, it is not considered to be an error if the group does not exist.

**Output**

This statement returns a confirmation of a successful operation.
alter interval

Purpose

Purpose  The purpose of the alter interval statement is to change properties of the specified interval.

Syntax

Syntax  The syntax for the alter interval statement is

\[
\text{alter [ existing | interval intervalname with WITHITEM {, WITHITEM]}
\]

WITHITEM:

- \(\text{base} = < \text{none} | \text{period} >\)
- \(\text{duration} = < \text{none} | \text{period} >\)
- \(\text{embedded} = < \text{none} | \text{intervalname} >\)
- \(\text{endtime} = < \text{none} | \text{datetime} >\)
- \(\text{filter} = \text{none}\)
- \(\text{filter} = (\text{intervalname}[, \text{intervalname}] )\)
- \(\text{< noinverse} | \text{inverse} >\)
- \(\text{selection} = \text{none}\)
- \(\text{selection} = (\text{IVAL_SELITEM}[, \text{IVAL_SELITEM}] )\)
- \(\text{starttime} = < \text{none} | \text{datetime} >\)
- \(\text{synctime} = \text{datetime}\)
- \(\text{group} = \text{groupname}\)

IVAL_SELITEM:

- \(< \text{signed_integer} | \text{datetime} | \text{datetime} - \text{datetime} >\)

Description

Description  The alter interval command is used to change an interval definition. For a detailed description of these options, refer to the create interval statement on page 94.

If the \text{existing} keyword has been specified, it is not considered to be an error if the interval does not exist.

Output

Output  This statement returns a confirmation of a successful operation
alter job

Purpose

The purpose of the alter job statement is to change properties of the specified job. This statement is used by job administrators, job servers, and by the job itself.

Syntax

The syntax for the alter job statement is

```
alter job jobid
with WITHITEM {, WITHITEM}

alter job
with WITHITEM {, WITHITEM}
```

WITHITEM:

```
< suspend | suspend restrict | suspend local | suspend local restrict >
| cancel
| clear warning
| comment = string
| error text = string
| exec pid = pid
| exit code = signed_integer
| exit state = statename [ force ]
| ext pid = pid
| ignore resource = ( id [, id] )
| kill
| nicevalue = signed_integer
| priority = integer
| renice = signed_integer
| rerun [ recursive ]
| resume
| < noresume | resume in period | resume at datetime >
| run = integer
| state = JOBSTATE
| timestamp = string
| warning = string
```

JOBSTATE:
The alter job command is used for several purposes. Firstly, job servers use this command to document the progress of a job. All the state transitions a job undergoes during the time when the job is the responsibility of a job server are performed using the alter job command.

Secondly, some changes such as ignoring dependencies or resources, as well as changing the priority of a job, are carried out manually by an administrator. The Exit State of a job in a Pending State can be set by the job itself or by a process that knows the job ID and key of the job that is to be changed.

**cancel**  The cancel option is used to cancel the addressed job and all non-Final Children. A job can only be cancelled if neither the job itself nor one of its children is active. Cancelling a running job will set the job in a cancelling state. The effective cancel is postponed until the job is finished.

If a Scheduling Entity is dependent upon the cancelled job, it can become unreachable. In this case the dependent job does not acquire the Unreachable Exit State defined in the Exit State Profiles, but is set as having the Job State ”Unreachable”. It is the operator’s task to restore this job back to the job state “Dependency Wait” by ignoring dependencies or even to cancel it.

Cancelled jobs are considered to be just like Final Jobs without a Final Exit. This means that the parents of a cancelled job become final without taking into consideration the Exit State of the cancelled job. In this case the dependent jobs of the parents continue running normally.

The cancel option can only be used by users.

**comment**  The comment option is used to document an action or to add a comment to the job. Comments can have a maximum length of 1024 characters. Any number of comments can be saved for a job.

Some comments are saved automatically. For example, if a job attains a Restartable State, a log is written to document this fact.
**error text**  The error text option is used to write error information about a job. This can be done by the responsible job server or a user. The server can write this text itself as well. This option is normally used if the job server cannot start the corresponding process. Possible cases are where it is not possible to switch to the defined working directory, if the executable program cannot be found, or when opening the error log file triggers an error.

**exec pid**  The exec pid option is used exclusively by the job server to set the process ID of the control process within the server.

**exit code**  The exit code option is used by the job server to tell the repository server with which Exit Code the process has finished. The repository server now calculates the matching Exit State from the Exit State Mapping that was used.

**exit state**  The exit state option is used by jobs in a pending state to set their state to another value. This is usually a Restartable or Final State. Alternatively, this option can be used by administrators to set the state of a non-final job. If the Force Flag is not being used, the only states that can be set are those which are theoretically attainable by applying the Exit State Mapping to any Exit Code. The set state must exist in the Exit State Profile.

**ext pid**  The ext pid option is used exclusively by the job server to set the process ID of the started user process.

**ignore resource**  The ignore resource option is used to revoke individual Resource Requests. The ignored resource is then no longer requested. If the parameters of a resource are being referenced, that resource cannot be ignored. If invalid IDs have been specified, it is skipped. All other specified resources are ignored. Invalid IDs in this context are the IDs of resources that are not requested by the job. The ignoring of resources is logged.

**ignore dependency**  The ignore dependency option is used to ignore defined dependencies. If the recursive flag is used, not only do the job or batch ignore the dependencies, but its children do so as well.

**kill**  The kill option is used to submit the defined Kill Job. If no Kill Job has been defined, it is not possible to forcibly terminate the job from within BICsuite. The job obviously has to be active, that means it must be running, killed or broken.active.
User Commands

alter job

The last two states are not regular cases. When a Kill Job has been submitted, the Job State is to_kill. After the Kill Job has terminated, the Job State of the killed job is set to killed unless it has been completed, in which case it is finished or final. This means that the job with the Job State killed is always still running and that at least one attempt has been made to terminate it.

nicevalue The nicevalue option is used to change the priority or the nicevalue of a job or batch and all of its children. If a child has several parents, any changes you make can, but do not necessarily have to, affect the priority of the child in the nicevalue of one of the parents. Where there are several parents, the maximum nicevalue is searched for.

This means that if Job C has three Parents P1, P2 and P3, whereby P1 sets a nice value of 0, P2 sets a nice value of 10 and P3 a nicevalue of -10, the effective nicevalue is -10. (The lower the nicevalue the better). If the nicevalue for P2 is changed to -5, nothing happens because the -10 of P3 is better than -5. If the nicevalue of P3 falls to 0, the new effective nicevalue for Job C is -5.

The nicevalues can have values between -100 and 100. Values that exceed this range are tacitly adjusted.

priority The priority option is used to change the (static) priority of a job. Because batches and milestones are not executed, priorities are irrelevant to them. Changing the priority only affects the changed job. Valid values lie between 0 and 100. In this case, 100 corresponds to the lowest priority and 0 is the highest priority.

When calculating the dynamic priority of a job, the scheduler begins with the static priority and adjusts it according to how long the job has already been waiting. If more than one job has the same dynamic priority, the job with the lowest job ID is scheduled first.

renice The renice option is similar to the nicevalue option with the difference that the renice option functions relatively while the nicevalue option functions absolutely. If some batches have a nicevalue of 10, a renice of -5 causes the nicevalue to rise to 5. (It rises because the lower the number, the higher the priority).

rerun The rerun option is used to restart a job in a Restartable State. If you attempt to restart a job that is not restartable, an error message is displayed. A job is restartable if it is in a Restartable State or it has the Job State error or broken_finished.

If the recursive flag has been specified, the job itself and all its direct and indirect children that are in a Restartable State are restarted. If the job itself is final, this is not considered to be an error. It is therefore possible to recursively restart batches.
The resume option is used to reactivate a suspended job or batch. There are two ways to do this. The suspended job or batch can either be reactivated immediately or a delay can be set. A delay can be achieved by specifying either the number of time units for the delay the time when the job or batch is to be activated. For details about specifying a time, refer to the overview on page 6. The resume option can be used together with the suspend option. Here, the job is suspended and then resumed again after (or at) a specified time.

The run option is used by the job server to ensure that the modified job matches the current version. Theoretically, the computer could crash after a job has been started by a job server. To complete the work, the job is manually restarted from another job server. After the first system has been booted, the job server can attempt to change the job state to broken_finished without knowing anything about what happened after the crash. Using the run option then prevents the wrong state from being set.

The state option is mainly used by job servers, but it can also be used by administrators. It is not recommended to do so unless you know exactly what you are doing. The usual procedure is that the job server sets the state of a job from starting to started, from started to running, and from running to finished. In the event of a crash or any other problems, it is possible for the job server to set the job state to broken_active or broken_finished. This means that the Exit Code of the process is not available and the Exit State has to be set manually.

The suspend option is used to suspend a batch or job. It always functions recursively. If a parent is suspended, its children are all suspended as well. The resume option is used to reverse the situation. The effect of the restrict option is that cwa resume can be done by members of the group ADMIN only.

The timestamp option is used by the job server to set the timestamps of the state transition in keeping with the local time from the perspective of job server.

This statement returns a confirmation of a successful operation. Output
User Commands

**alter job definition**

**Purpose**

The purpose of the alter job definition statement is to change properties of the specified job definition.

**Syntax**

The syntax for the alter job definition statement is

```
alter [ existing ] job definition folderpath . jobname
```

```
with WITHITEM {, WITHITEM}
```

```
alter [ existing ] job definition folderpath . jobname
```

```
AJD_ADD_DEL_ITEM {, AJD_ADD_DEL_ITEM}
```

**WITHITEM:**

```
children = none
```

```
| children = ( JOB_CHILDDEF {, JOB_CHILDDEF} )
```

```
dependency mode = < all | any >
```

```
environment = environmentname
```

```

The alter job definition command has two different variants. Description

- The first is similar to the create job definition statement and is used to redefine the job definition. All the affected options are overwritten. All the unaddressed options remain as they are.
- The second variant is used to add, edit or delete entries from the lists of children, resource requests, dependencies or parameters.
User Commands

alter job definition

The options are described in detail in the create job definition command on page 98. This also applies for the options in the child, resource request, dependency and parameter definitions.

If the existing keyword is being used, an error is not triggered if the addressed job definition does not exist. The same applies if the existing keyword is being used while the list entries are being deleted or edited.

Output

Output This statement returns a confirmation of a successful operation
alter named resource

Purpose

The purpose of the alter named resource statement is to change its properties.

Syntax

The syntax for the alter named resource statement is

```plaintext
alter [existing] named resource resourcepath
with WITHITEM {, WITHITEM}
```

WITHITEM:

- `group = groupname [ cascade ]`
- `inherit grant = none`
- `inherit grant = ( PRIVILEGE {, PRIVILEGE} )`
- `parameter = none`
- `parameter = ( PARAMETER {, PARAMETER} )`
- `state profile = < none | rspname >`

PRIVILEGE:

- `create content`
- `drop`
- `edit`
- `execute`
- `monitor`
- `operate`
- `resource`
- `submit`
- `use`
- `view`

PARAMETER:

- `parametername constant = string`
- `parametername local constant [ = string ]`
- `parametername parameter [ = string ]`
User Commands

alter named resource

Description

The alter named resource statement is used to change the properties of the Named Resource. For a detailed description of the options, refer to the description of the create named resource statement on page 116. If the existing keyword has been specified, attempting to modify a non-existent Named Resource will not trigger an error.

Output

This statement returns a confirmation of a successful operation.
The purpose of the alter resource statement is to change properties of resources.

Syntax

The syntax for the alter resource statement is

```
alter [existing] RESOURCE_URL
with WITHITEM {, WITHITEM}
```

**RESOURCE_URL:**

- `resource resourcepath in folderpath`
- `resource resourcepath in serverpath`

**WITHITEM:**

- `amount = < infinite | integer >`
- `< online | offline >`
- `parameter = none`
- `parameter = ( PARAMETER {, PARAMETER} )`
- `requestable amount = < infinite | integer >`
- `state = statename`
- `touch [ = datetime ]`
- `group = groupname`

**PARAMETER:**

- `parametername = < string | default >`

Description

The alter resource statement is used to change the properties of resources. For a detailed description of the options, refer to the description of the create resource statement on page 119.

If the `existing` keyword has been specified, attempting to modify a non-existent resource will not trigger an error.

Output

This statement returns a confirmation of a successful operation.
**alter resource state mapping**

**Purpose**

The purpose of the alter resource state mapping statement is to change properties of the mapping.

**Syntax**

The syntax for the alter resource state mapping statement is

```
alter [ existing ] resource state mapping mappingname
with map = ( WITHITEM {, WITHITEM} )
```

**Description**

The alter resource state mapping statement is used to change the properties of the Resource State Mapping. For a detailed description of the options, refer to the description of the create resource state mapping statement on page 123. If the **existing** keyword has been specified, attempting to modify a non-existent Resource State Mapping will not trigger an error.

**Output**

This statement returns a confirmation of a successful operation
alter resource state profile

Purpose

The purpose of the alter resource state profile statement is to change properties of the specified resource state profile.

Syntax

The syntax for the alter resource state profile statement is

```
alter [existing] resource state profile profilename with WITHITEM {, WITHITEM}
```

WITHITEM:

```
  initial state = statename
  | state = ( statename {, statename} )
```

Description

The alter resource state profile statement is used to change the properties of the Resource State Profile. For a detailed description of the options, refer to the description of the Resource State Profile statement on page 124.

If the existing keyword has been specified, attempting to modify a non-existent Resource State Profile does not return an error.

Output

This statement returns a confirmation of a successful operation.
**alter schedule**

**Purpose**

*Purpose*  The purpose of the alter schedule statement is to change properties of the specified schedule.

**Syntax**

*Syntax*  The syntax for the alter schedule statement is

```
alter [ existing ] schedule schedulepath
    with WITHITEM {, WITHITEM}
```

**Description**

*Description*  The alter schedule statement is used to change the properties of a schedule. For a detailed description of the options for the create schedule statement, refer to page 125.

If the **existing** keyword has been specified, attempting to modify a non-existent schedule will not trigger an error.
Output

This statement returns a confirmation of a successful operation
User Commands

**alter scheduled event**

**Purpose**

The purpose of the alter scheduled event statement is to change properties of the specified scheduled event.

**Syntax**

The syntax for the alter scheduled event statement is

```
alter [ existing ] scheduled event schedulepath . eventname
with WITHITEM {, WITHITEM}
```

**Description**

The alter scheduled event statement is used to change the properties of a specified Scheduled Event. For a detailed description of the options for the create scheduled event statement, refer to page 127. If the `existing` keyword has been specified, attempting to modify a non-existent Scheduled Event does not return an error.

**Output**

This statement returns a confirmation of a successful operation.
alter scope

Purpose

The purpose of the alter scope statement is to change the properties of the specified scope.

Syntax

The syntax for the alter scope statement is

\[
\text{alter [existing] < scope serverpath | job server serverpath >}
\]
\[
\text{with} \ \text{JS\_WITHITEM} \ \{, \ \text{JS\_WITHITEM}\}
\]

\[
\text{alter [existing] job server }
\]
\[
\text{with} \ < \ \text{fatal} | \ \text{nonfatal} > \ \text{error text} = \text{string}
\]

\[
\text{alter [existing] job server }
\]
\[
\text{with} \ \text{dynamic} \ \text{PARAMETERS}
\]

\[
\text{JS\_WITHITEM}:
\]
\[
\text{config} = \text{none}
\]
\[
\text{config} = \ ( \ \text{CONFIGITEM} \ \{, \ \text{CONFIGITEM}\} \ )
\]
\[
\text{< enable | disable >}
\]
\[
\text{error text} = \ < \ \text{none} | \ \text{string} >
\]
\[
\text{group} = \text{groupname} \ [\ \text{cascade}\ ]
\]
\[
\text{inherit grant} = \text{none}
\]
\[
\text{inherit grant} = \ ( \ \text{PRIVILEGE} \ \{, \ \text{PRIVILEGE}\} \ )
\]
\[
\text{node} = \text{nodename}
\]
\[
\text{parameter} = \text{none}
\]
\[
\text{parameter} = \ ( \ \text{PARAMETERITEM} \ \{, \ \text{PARAMETERITEM}\} \ )
\]
\[
\text{password} = \text{string}
\]
\[
\text{rawpassword} = \text{string} \ [\ \text{salt} = \text{string} ]
\]

\[
\text{PARAMETERS}:
\]
\[
\text{parameter} = \text{none}
\]
\[
\text{parameter} = \ ( \ \text{PARAMETERSPEC} \ \{, \ \text{PARAMETERSPEC}\} \ )
\]

\[
\text{CONFIGITEM}:
\]
\[
\text{parametername} = \text{none}
\]
\[
\text{parametername} = \ ( \ \text{PARAMETERSPEC} \ \{, \ \text{PARAMETERSPEC}\} \ )
\]
User Commands

alter scope

| parametername = < string | number >

PRIVILEGE:
- create content
- drop
- edit
- execute
- monitor
- operate
- resource
- submit
- use
- view

PARAMETERITEM:
- parametername = dynamic
- parametername = < string | number >

PARAMETERSPEC:
- parametername = < string | number >

Description

Description
The alter scope command is a user command. This command is used to modify the configuration or other properties of a scope.

Output

Output
This statement returns a confirmation of a successful operation.
**alter server**

**Purpose**

The purpose of the alter server statement is to enable or disable user connections, or to define the trace level.

**Syntax**

The syntax for the alter server statement is

```
alter server with < enable | disable > connect

alter server with schedule

alter server with trace level = integer
```

**Description**

The alter server command can be used to turn the function for connecting to the server on and off. If this function has been disabled, only the user “System” can connect to the server.

The alter server command is also used to define the logged types of server messages. The following information types are defined:

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fatal</td>
<td>A fatal error has occurred. The server is run down.</td>
</tr>
<tr>
<td>Error</td>
<td>An error has occurred.</td>
</tr>
<tr>
<td>Info</td>
<td>An important informational message that was not written due to an error.</td>
</tr>
<tr>
<td>Warning</td>
<td>A warning.</td>
</tr>
<tr>
<td>Message</td>
<td>An informative message.</td>
</tr>
<tr>
<td>Debug</td>
<td>Messages that can be used for troubleshooting.</td>
</tr>
</tbody>
</table>

Fatal messages, error messages and info messages are always written to the server log file. Warnings are written if the trace level is 1 or higher, normal messages are written if the trace level is 2 or higher. Debug messages provide a lot of output and are returned for trace level 3.

**Output**

This statement returns a confirmation of a successful operation.
User Commands

**alter session**

**Purpose**

*Purpose* The purpose of the alter session statement is to specify the used protocol, the session timeout value or the trace level for the specified session.

**Syntax**

*Syntax* The syntax for the alter session statement is

```sql
alter session

with

WITHITEM

{

WITHITEM

}

WITHITEM:

command = (sdms-command)

| protocol = PROTOCOL

| session = string

| timeout = integer

| < trace | notrace >

| trace level = integer

PROTOCOL:

json

| line

| perl

| python

| serial

| xml
```

**Description**

*Description* The alter session command can be used to enable and disable the trace. If the trace is enabled, all the issued commands are logged in the log file. A communication protocol can also be selected. An overview of the currently defined protocols is shown in the table below.

<table>
<thead>
<tr>
<th>Protokoll</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Line</td>
<td>Plain ASCII output</td>
</tr>
<tr>
<td>Perl</td>
<td>The output is offered as a Perl structure that can be easily evaluated by the Perl script using eval.</td>
</tr>
<tr>
<td>Python</td>
<td>Like Perl, but this is a Python structure.</td>
</tr>
<tr>
<td>Serial</td>
<td>Serialized Java objects.</td>
</tr>
<tr>
<td>Xml</td>
<td>Outputs an xml structure.</td>
</tr>
</tbody>
</table>

The timeout parameter for the session can be set as a last resort. A timeout of 0 means that no timeout is active. Any number greater than 0 indicates the number of seconds after which a session is automatically disconnected.

**Output**

This statement returns a confirmation of a successful operation
User Commands

alter trigger

**Purpose**

The purpose of the alter trigger statement is to change properties of the specified trigger.

**Syntax**

The syntax for the alter trigger statement is

```
alter [existing] trigger triggername on TRIGGEROBJECT [ <noinverse | inverse > ]
with WITHITEM {, WITHITEM}
```

**TRIGGEROBJECT:**

- `resource resourcepath in folderpath`
- `job definition folderpath`
- `object monitor objecttypename`
- `resource resourcepath in serverpath`

**WITHITEM:**

- `< active | inactive >`
- `< nowarn | warn >`
- `limit state = < none | statename >`
- `< nomaster | master >`
- `rerun`
- `< noresume | resume in period | resume at datetime >`
- `state = none`
- `state = ( < statename {, statename} | CT_RSCSTATUSITEM {, CT_RSCSTATUSITEM} )`
- `submit after folderpath`
- `submit folderpath`
- `submitcount = integer`
- `< nosuspend | suspend >`
- `[ type = ] CT_TRIGGERTYPE`
- `group = groupname`

**CT_EVENT:**

- `< create | change | delete >`

**CT_RSCSTATUSITEM:**
alter trigger statement is used to change the properties of a defined trigger. If the existing keyword has been specified, changing an existing trigger will not return an error. For a detailed description of these options, refer to the create trigger statement on page 132.

**Output**

This statement returns a confirmation of a successful operation.
alter user

Purpose

The purpose of the alter user statement is to change properties of the specified user.

Syntax

The syntax for the alter user statement is

\[
\text{alter [ existing ] user username with \{, WITHITEM\}}
\]

\[
\text{alter [ existing ] user username ADD_{DELITEM} \{, ADD_{DELITEM}\}}
\]

WITHITEM:
- \text{default group = groupname}
- < enable | disable >
- \text{group = ( groupname {, groupname} )}
- \text{password = string}
- \text{rawpassword = string [ salt = string ]}

ADD_{DELITEM}:
- < add | delete > group = ( groupname {, groupname} )

Description

The alter user statement is used to change the properties of a defined user. If the \text{existing} keyword has been specified, attempting to modify a non-existent user will not trigger an error.

For a detailed description of these options, refer to the create user statement on page 140.

The second variant of the statement is used to delete or add the user from or to the specified groups.

Output

This statement returns a confirmation of a successful operation

alter user
4. connect commands
User Commands  

connect

**connect**

**Purpose**

*Purpose*  The purpose of the connect statement is to authenticate a user to the server.

**Syntax**

*Syntax*  The syntax for the connect statement is

```
connect username identified by string [ with WITHITEM {, WITHITEM} ]
```

*WITHITEM:*

```
command = ( sdms-command )
| protocol = PROTOCOL
| session = string
| timeout = integer
| < trace | notrace >
| trace level = integer
```

*PROTOCOL:*

```
json
| line
| perl
| python
| serial
| xml
```

**Description**

*Description*  The connect command is used to authenticate the connected process on the server to. A communication protocol can be optionally specified. The default protocol is line.

The selected protocol defines the output format. All protocols except for serial return ASCII output. The protocol serial returns a serialized Java object.

An executable command can also be returned when the connection is established. In this case, the output of the accompanying command is used as the output for the connect command. If the command fails, but the connect was successful, the connection remains active.

An example for all protocols except the serial protocol is given below.

---

72                      connect
**The line protocol**  The line protocol only returns an ASCII text as the result from a command.

```text
connect donald identified by 'duck' with protocol = line;

Connect

CONNECT_TIME : 19 Jan 2005 11:12:43 GMT

Connected

SDMS>
```

**The XML protocol**  The XML protocol returns an XML structure as the result from a command.

```xml
<OUTPUT>
  <DATA>
    <TITLE>Connect</TITLE>
    <RECORD>
      <CONNECT_TIME>19 Jan 2005 11:15:16 GMT</CONNECT_TIME>
    </RECORD>
  </DATA>
  <FEEDBACK>Connected</FEEDBACK>
</OUTPUT>
```

**The python protocol**  The python protocol returns a Python structure that can be evaluated using the Python eval function.

```python
connect donald identified by 'duck' with protocol = python;
{'DATA':
  {'TITLE': 'Connect',
   'DESC': [
     'CONNECT_TIME'
   ],
   'RECORD': {
     'CONNECT_TIME': '19 Jan 2005 11:16:08 GMT'}
 },
  'FEEDBACK': 'Connected'
}
```

**The perl protocol**  The perl protocol returns a Perl structure that can be evaluated using the Perl eval function.

```perl
connect donald identified by 'duck' with protocol = perl;

{'DATA' =>
  }
```
User Commands

connect

'TITLE' => 'Connect',
'DESC' => [
'CONNECT_TIME'
],
'RECORD' => {
'CONNECT_TIME' => '19 Jan 2005 11:19:19 GMT'}
,'FEEDBACK' => 'Connected'

Output

This statement returns a confirmation of a successful operation
5. copy commands
User Commands  copy folder

**copy folder**

**Purpose**

The purpose of the copy folder statement is to copy a folder including all contents to some other place in the folder hierarchy.

**Syntax**

The syntax for the copy folder statement is

```plaintext
copy FOLDER_OR_JOB {, FOLDER_OR_JOB} to folderpath

copy FOLDER_OR_JOB {, FOLDER_OR_JOB} to foldername

FOLDER_OR_JOB:
[ < folder folderpath | job definition folderpath > ]
```

**Description**

If a folder has been copied, every object in the folder is copied as well. If there are any relationships between objects that were copied as the result of a folder copy operation (e.g. dependencies, children, triggers, etc.), these are changed accordingly and mapped to the resulting objects from the copy.

For example, if a folder SYSTEM.X.F containing two jobs A and B, and with SYSTEM.X.F.B dependent upon SYSTEM.X.F.A, is copied to the folder SYSTEM.Y, the newly created job SYSTEM.Y.F.B will be dependent upon the newly created job SYSTEM.Y.F.A.

Note that if the jobs were copied using a copy job definition command, the new job SYSTEM.Y.F.B would still be dependent upon SYSTEM.X.F.A. This may not correspond to the user’s view.

**Output**

This statement returns a confirmation of a successful operation.
**copy named resource**

**Purpose**

The purpose of the copy named resource statement is to copy a named resource into another category.

**Syntax**

The syntax for the copy named resource statement is

```
copy named resource resourcepath to resourcepath
```

```
copy named resource resourcepath to resourcename
```

**Description**

The copy named resource command is used to save a copy of a Named Resource or an entire category.

If the specified target resourcepath already exists as a category, a Named Resource or category with the same name as the source object is created within this category.

If the specified target resourcepath already exists as a Named Resource, this is regarded as an error.

**Output**

This statement returns a confirmation of a successful operation.
User Commands  

**copy scope**

**Purpose**

*Purpose*  The purpose of the copy scope statement is to copy a scope including all contents to some other place within the scope hierarchy.

**Syntax**

*Syntax*  The syntax for the copy scope statement is

\[
\text{copy} \ < \text{scope serverpath} \mid \text{job server serverpath} > \ \text{to serverpath}
\]

\[
\text{copy} \ < \text{scope serverpath} \mid \text{job server serverpath} > \ \text{to scopename}
\]

**Description**

*Description*  The copy named resource command is used to save a copy of entire scopes. This copy also includes the resource and parameter definitions. If the specified target servicepath already exists as a scope, a scope with the same name as the source object is created within this category. If the specified target serverpath already exists as a job server, this is regarded as an error. Since a job server is only regarded as a special type of scope, it is possible to copy job servers using this command. In this case, this command is identical to the copy job server command.

**Output**

*Output*  This statement returns a confirmation of a successful operation
6. create commands
User Commands  

create comment

create comment

Purpose

The purpose of the create comment statement is to store a comment for the specified object.

Syntax

The syntax for the create comment statement is

```
create [ or alter ] comment on OBJECTURL
  with CC_WITHITEM
```

OBJECTURL:

```
distribution distributionname for pool resourcopath in serverpath
  | environment environmentname
  | exit state definition statename
  | exit state mapping mappingname
  | exit state profile profilename
  | event eventname
  | resource resourcopath in folderpath
  | folder folderpath
  | footprint footprintname
  | group groupname
  | interval intervalname
  | job definition folderpath
  | job jobid
  | named resource resourcopath
  | parameter parametername of PARAM_LOC
  | resource state definition statename
  | resource state mapping mappingname
  | resource state profile profilename
  | scheduled event schedulepath . eventname
  | schedule schedulepath
  | resource resourcopath in serverpath
  | < scope serverpath | job server serverpath >
  | trigger trigername on TRIGGEROBJECT [ < noinverse | inverse > ]
  | user username
```

CC_WITHITEM:

```
CC_TEXTITEM {, CC_TEXTITEM}
```
create comment

| url = string

PARAM_LOC:
- folder folderpath
- job definition folderpath
- < scope serverpath | job server serverpath >

TRIGGEROBJECT:
- resource resourcepath in folderpath
- job definition folderpath
- object monitor objecttypename
- resource resourcepath in serverpath

CC_TEXTITEM:
- tag = < none | string > , text = string
- text = string

Description

The create comment statement is used to create the condensed description or the URL of the description for the object to be commented on. The optional keyword or alter is used to update the comment (if one exists). If it is not specified, the presence of a comment will trigger an error.

Output

This statement returns a confirmation of a successful operation
create environment

Purpose
Purpose
The purpose of the create environment statement is to define a set of static named resources which are needed in the scope a job wants to run.

Syntax
Syntax
The syntax for the create environment statement is

```plaintext
create [ or alter | environment environmentname [ with 
ENV_WITH_ITEM ]

ENV_WITH_ITEM:
  resource = none
  | resource = ( ENV_RESOURCE {, ENV_RESOURCE} )

ENV_RESOURCE:
  resourcepath [ < condition = string | condition = none > ]
```

Description
Description
The create environment statement is used to define a series of Static Resource Requests which describe the requisite environment that a job needs. Since the environments cannot be created by ordinary users, and jobs have to describe the environment that they require to run, environments can be used to force jobs to use a specific job server.

Resources
Resources
The Resources clause is used to specify the Required (Static) Resources. Specified resources that are not static will trigger an error. Since only static resources are specified, no further information is required. It is permissible to specify an empty environment (an environment without resource requests). This is not advisable, though, because it means a loss of control.

Output
Output
This statement returns a confirmation of a successful operation
create event

Purpose

The purpose of the create event statement is to define an action which can be executed by the time scheduling engine.

Syntax

The syntax for the create event statement is

```
create [ or alter ] event eventname
with EVENT_WITHITEM { , EVENT_WITHITEM }
```

```
EVENT_WITHITEM:
  action =
    submit folderpath [ with parameter = ( PARAM { , PARAM } ) ]
  | group = groupname

PARAM:
  parametername = < string | number >
```

Description

The create event statement is used to define an action that can be scheduled by the Time Scheduling module. The defined action is the submission of a master submittable job or batch.

**action** The submit part of the statement is a restricted variant of the submit command (see page 354).

**group** The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

Output

This statement returns a confirmation of a successful operation.
**create exit state definition**

**Purpose**

The purpose of the create exit state definition statement is to create a symbolic name for the state of a job.

**Syntax**

The syntax for the create exit state definition statement is

```
create [ or alter ] exit state definition statename
```

**Description**

The create exit state definition statement is used to create a symbolic name for the Exit State of a job, milestone or batch. The optional keyword *or alter* is used to prevent error messages from being triggered and the current transaction from being aborted if an Exit State Definition already exists. This is particularly useful in conjunction with multicommands. If it is not specified, the existence of an Exit State Definition with the specified name will trigger an error.

**Output**

This statement returns a confirmation of a successful operation.

**Example**

In the following examples, symbolic names have been created for Job States.

```plaintext
create exit state definition success;
create exit state definition error;
create exit state definition reached;
create exit state definition warning;
create exit state definition wait;
create exit state definition skip;
create exit state definition unreachable;
```
create exit state mapping

Purpose

The purpose of the create exit state mapping statement is to create a mapping between the numerical exit code of a process and a symbolic exit state.

Syntax

The syntax for the create exit state mapping statement is

```
create [ or alter ] exit state mapping mappingname
with map = ( statename { , signed_integer , statename } )
```

Description

The create exit state mapping statement defines the mapping of Exit Codes to logical Exit States. The simplest form of this statement only specifies one Exit State. This means that the job automatically reaches this Exit State after it has finished regardless of its Exit Code. More complex definitions specify more than one Exit State and at least one delimitation.

Output

This statement returns a confirmation of a successful operation.

Example

The example below shows a relatively simple, yet realistic mapping of Exit Codes to logical Exit States.

The statement

```
create exit state mapping example1
with map = ( error,
            0, success,
            1, warning,
            4, error);
```

defines the following mapping:

<table>
<thead>
<tr>
<th>Exit Code Range from</th>
<th>Exit Code Range to</th>
<th>Resultant Exit State</th>
</tr>
</thead>
<tbody>
<tr>
<td>−∞</td>
<td>-1</td>
<td>error</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>success</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>warning</td>
</tr>
<tr>
<td>4</td>
<td>∞</td>
<td>error</td>
</tr>
</tbody>
</table>
create exit state profile

Purpose

The purpose of the create exit state profile statement is to define a set of valid exit states.

Syntax

The syntax for the create exit state profile statement is

```plaintext
create [ or alter | exit state profile ] profilename
with WITHITEM {, WITHITEM}

WITHITEM:
  default mapping = < none | mappingname >
  | force
  | state = ( ESP_STATE {, ESP_STATE} )

ESP_STATE:
  statename < final | restartable | pending > [ OPTION { OPTION} ]

OPTION:
  < unreachable | broken | batch default | dependency default >
```

Description

The create exit state profile statement is used to define a quantity of valid Exit States for a job, milestone or batch.

**default mapping**  With the default mapping clause it is possible to define which Exit State Mapping is to be used if no other mapping has been specified. This makes it considerably easier to create jobs.

**force**  While an Exit State Profile is being created, the force option has no effect and is ignored. If or alter is specified and the Exit State Profile that you want to create already exists, the force option delays the integrity check until later.

**state**  The state clause defines which Exit State Profiles are valid within this definition. Each Exit State Definition must be classified as being final, restartable or pending. If a job has reached the final state it can no longer be started, which means that the state can no longer change. If a job has reached the restartable state,
it can be started again. This means that the state of such a job can change as well. **pending** means that a job cannot be restarted, but it is not final either. The state must be set externally.

The order in which the Exit States are defined is relevant. The first specified Exit State has the highest preference, while the most recently specified Exit State has the lowest preference. Normally, **final** states are specified later than **restartable** states. A state’s preference is used to decide which state is visible when several different Exit States of children are merged.

Just one Exit State can be declared as being an **unreachable** state. This means that a job, batch or milestone with this profile is mapped to the specified state as soon as it has become unreachable. This Exit State must be **final**.

A maximum of one Exit State within a profile can be designated as being a **broken** state. This means that a job will reach this state as soon as it has switched to the **error** or **broken_finished** state. This can be handled using a trigger. The Exit State that is defined as being a **broken** state must be **restartable**.

A maximum of one state can be declared as being a **batch default** state. An empty batch assumes this status. This allows for an explicit deviation from the standard behaviour. If no status is designated as being **batch default**, an empty batch will automatically assume the final status with the lowest preference that is not designated as being **unreachable**. If such a status does not exist, the **unreachable** state is also considered a candidate.

Any number of Final States can be designated as **dependency default** states. Dependencies that define a default dependency are fulfilled if the required job assumes one of the states designated as **dependency default**.

### Output

This statement returns a confirmation of a successful operation

### Example

These examples show how the Exit State Profiles `example_1` and `example_2` are created.

In the first, very simple example, the Exit State of **success** is to be a Final State.

```plaintext
create exit state profile example_1
with
    state = ( success final );
```

In the second example, the Exit State **failure** is defined as being restartable. This state has a higher priority than the (final) state **success** and must therefore be listed as the first state.

```plaintext
create exit state profile example_2
with
    state = ( failure restartable,
```
User Commands

create exit state profile

  success final

);
create folder

Purpose

The purpose of the create folder statement is to create a container for job definitions and/or other folders.

Syntax

The syntax for the create folder statement is

```
create [ or alter ] folder folderpath [ with WITHITEM {, WITHITEM} ]
```

WITHITEM:

- `environment = < none | environmentname >`
- `group = groupname [ cascade ]`
- `inherit grant = none`
- `inherit grant = ( PRIVILEGE {, PRIVILEGE} )`
- `parameter = none`
- `parameter = ( parametername = string {, parametername = string} )`

PRIVILEGE:

- `create content`
- `drop`
- `edit`
- `execute`
- `monitor`
- `operate`
- `resource`
- `submit`
- `use`
- `view`

Description

This command creates a folder and has the following options:

**environment option**  If an environment has been assigned to a folder, every job in the folder and its subfolders will inherit all the Resource Requests from the Environment Definition.
User Commands

create folder

group option  The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

parameter option  The parameter option can be used to define key/value pairs for the folder. The complete list of parameters must be specified within a command.

inherit grant option  The inherit grants clause allows you to define which privileges are to be inherited through the hierarchy. If this clause is not specified, all privileges are inherited by default.

Output

Output  This statement returns a confirmation of a successful operation
**create footprint**

**Purpose**

The purpose of the create footprint statement is to create a set of often used system resource requirements.

**Syntax**

The syntax for the create footprint statement is

```
create [ or alter ] footprint footprintname
with resource = ( REQUIREMENT { , REQUIREMENT } )
```

**Description**

The create footprint command creates a set of Resource Requests which can be reused. The Required Resources are all System Resources. The Required Resources are described by their names, a set with zero by default, and optionally a keep option.

**keep** The keep option in a Resource Request defines the time when the resource is released. The keep option is valid for both System and Synchronizing Resources. There are three possible values. Their meanings are explained in the table below:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>nokeep</td>
<td>The resource is released at the end of the job. This is the default behaviour.</td>
</tr>
<tr>
<td>keep</td>
<td>The resource is released as soon as the job has reached the Final State.</td>
</tr>
<tr>
<td>keep final</td>
<td>The resource is released when the job and all its children are final.</td>
</tr>
</tbody>
</table>
User Commands  create footprint

**amount**  The amount option is only valid with requests for Named Resources of the type “System” or “Synchronizing”. The amount in a Resource Request expresses how many units of the Required Resource are allocated.

**Output**

*Output*  This statement returns a confirmation of a successful operation
create group

Purpose

The purpose of the create group statement is to create an object to which privileges can be granted.

Syntax

The syntax for the create group statement is

```
create [ or alter ] group groupname [ with WITHITEM ]
```

WITHITEM:

```
user = none
| user = ( username {, username} )
```

Description

The create group statement is used to create a group. If the `or alter` keyword has been specified, an already existing group is changed. Otherwise, an already existing group is considered an error.

`user` The `user` clause is used to specify which users are group members.

Output

This statement returns a confirmation of a successful operation.
User Commands

create interval

create interval

Purpose

The purpose of the create interval statement is to define a periodic or aperiodic pattern at which events can, must not, be triggered.

Syntax

The syntax for the create interval statement is

create [ or alter ] interval intervalname [ with WITHITEM {, WITHITEM} ]

WITHITEM:

  base = < none | period >
  | duration = < none | period >
  | embedded = < none | intervalname >
  | endtime = < none | datetime >
  | filter = none
  | filter = ( intervalname {, intervalname} )
  | < noinverse | inverse >
  | selection = none
  | selection = ( IVAL_SELITEM {, IVAL_SELITEM} )
  | starttime = < none | datetime >
  | synctime = datetime
  | group = groupname

IVAL_SELITEM:

  < signed_integer | datetime | datetime - datetime >

Description

The intervals are the core of the Time Scheduling. They can regarded as block patterns. These patterns can be periodic or non-periodic. Within a period (Base) which, in the case of a non-periodic interval, has a length infinity (\(\infty\)), there are blocks of a predetermined length Duration. The last block may be incomplete if the period length is not an integer multiple of the duration is. The duration can also have a length \(\infty\). This means that the blocks have the same length as the periods.

It is not necessary for all of the blocks to be actually present. You can choose which blocks are present. This choice can be made by specifying the block number relative to the beginning or end of a period (1, 2, 3 or \(-1, -2, -3\)) or by stating “from - to” (all days between 3.4. and 7.6).
This results in complex patterns as shown in Figure 6.2.
The selection is 1-based, i.e. the first block has the number 1. The last block is
addressed with the number -1. This means that a block 0 does not exist.
Essentially, an interval can be described using the following parameters: Base fre-
quency (period length), duration and selection. Since an interval does not neces-
sarily always have to be valid, a start and end time can still be specified.

**Infinite intervals**  With a non-periodic interval without a duration (infinity), the
start time plays a special role: it then defines the only positive edge of this interval.
Similarly, an end time defines the only negative edge.
When a selection is made, this respectively results in blocks being created. The
selection "-0315T18:40" creates a block from 18:40 to 18:41 every year on March 15.
Selecting blocks using the position (first, second, etc.) is, of course, nonsense. This
is also ignored for infinite intervals.

**Inverse**  If, for example, the time between Christmas and New Year has been pos-
itively defined for a particular purpose, at the moment there is no way to easily
define the complementary time. In this example this is not a serious problem, but
with more complex patterns this incapability will result in complex and error-prone
dual definitions.
For this reason, an Inverse flag has been implemented which causes the specified
selection list to be interpreted complementarily, i.e. only those blocks that would
not have been chosen without a set invert flag are selected. In the case of the last
working day of the month, the inverse flag is set on all working days except for the
last working day of that month.
**Filter** The selection of blocks can be restricted even further. For example, if you have defined an interval “day of the month” (i.e. the base is one month, the duration is one day) and then selected the second block, such an interval would have a block on the respective second day of a month. If you want to define this only for the odd months (January, March, May, etc.), that would not be possible without a filter function because of the leap years.

The solution to the problem is to define a further interval (month of the year) with the selection 1, 3, 5, 7, 9, 11. This interval is then specified as a filter for the first interval.

Here, the first interval only shows a block if the second interval also shows a block at that “time”.

If several intervals have been specified as a filter, it is sufficient for one of these intervals to have a block at the required time (OR). To map an AND relationship between the filter intervals, the filter intervals are created as a chain (A filters B C filters, etc.). The order of the filters is not important.

**Embedded** Unfortunately, the world is not always so simple. In particular, it is not inconsequential whether you first perform an operation and then make a selection, or if you have to choose first and then perform the operation. In other words, there is a big difference if you talking about the last day of the month - if this is a working day - or about the last working day of the month.

We obviously also want to include this possibility for making a differentiation in our model. An **embedding** functionality has been implemented for this purpose. Here, we begin by taking over all the parameters for the embedded interval. This is followed by an evaluation of the selection list. Although it is allowed, selecting a “from - to” period is obviously senseless since this functionality can also be achieved with simple multiplication. Much more interesting is the possibility of making a relative selection. If the working days in a month are embedded and then the day −1 is selected, for instance, overall we now have an interval that defines the last working day of each month. If, on the other hand, the interval with the working days in a month is multiplied by an interval that returns the last day of a month, we will only get a hit if the last day of the month is a working day.

Embedding can therefore also be understood as follows: When selecting the blocks, not all of the embedded blocks are considered (and above all counted), but only the **active** blocks.

**Synchronisation** What have still not been taken into consideration are those situations involving multiple single periods. A period of 40 days, for example, could have its rising edge at midnight (00:00) on any day. That is why a synchronisation time (**synctime**) has been implemented which selects the earliest edge that is ≥ this point in time. If no such time has been explicitly specified, the date when the definition was created (**create**) is used.
Fundamentally, the first block of a period initially starts at its beginning. In cases where this is not possible (period = ∞, duration > period, Period XOR Duration have the unit “week”), the beginning of the period is used as the synchronisation time. If this is not possible either (period = ∞), the normal synchronisation time is used. The result of this approach is that the first block of a period may be incomplete as well (and is then never active).

Output

This statement returns a confirmation of a successful operation.
User Commands  

create job definition

create job definition

Purpose

The purpose of the create job definition statement is to create a scheduling entity object which can be submitted, standalone or as part of a larger hierarchy.

Syntax

The syntax for the create job definition statement is

```
create [ or alter ] job definition folderpath . jobname
with WITHITEM { , WITHITEM }
```

WITHITEM:

- children = none
- children = ( JOB_CHILDDEFF { , JOB_CHILDDEFF } )
- dependency mode = < all | any >

**Description**

This command creates or optionally modifies job, batch or milestone definitions. Since jobs, batches and milestones have a lot in common, in the following we have mainly used the general technical term “Scheduling Entity” whenever the behaviour is the same for all three types of job definitions. The expressions “job”, “batch” and “milestone” are used for Scheduling Entities of the corresponding type Job, Milestone and Batch.

If the “or alter” modifier is being used, the command (if a Scheduling Entity of the same name already exists) changes it according to the specified options.

**aging** The aging describes how quickly the priority is upgraded.

**children** The Children section of a job definition statement defines a list of child objects and is used to build up a hierarchy that enables the modelling of complex job structures.

Whenever a Scheduling Entity is submitted, all the static children are recursively submitted.

In addition, children that are not static can be submitted during the execution be a Running Job or Trigger.

The children are then specified using a comma-separated list of Scheduling Entity path names and additional properties.

The properties of the Child Definitions are described below:

**ALIAS** This option allows the implementation of the submitted jobs to be kept independent of the folder structure, and it will function regardless of whether objects are moved within the folder structure.
The alias for a Child Definition is only used when jobs submit dynamic children.

**IGNORE DEPENDENCY** Dependencies of parent jobs are normally inherited by their children. In some rare situations this is undesirable. In this case the **ignore dependency** option can be used to ignore such dependencies.

**MERGE MODE** A single Scheduling Entity can be used as a child of more than one Parent Scheduling Entity. If two or more such parents are part of a Master Run, the same children are repeatedly instantiated within this Master Run. This is not always a desirable situation. Setting the Merge Mode controls how the system handles this scenario.

The following table gives an overview of the possible Merge Modes and their meanings:

<table>
<thead>
<tr>
<th>merge mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nomerge</td>
<td>A duplicate instance of the Scheduling Entity is created. This is the default behaviour.</td>
</tr>
<tr>
<td>merge global</td>
<td>A duplicate instance is not created. A link is created between the Parent Submitted Entity and the already existing Child Submitted Entity.</td>
</tr>
<tr>
<td>merge local</td>
<td>Like Merge Global, but only Submitted Entities that were created in a single submit are merged.</td>
</tr>
<tr>
<td>failure</td>
<td>The submit attempting to create a duplicate Submitted Entity fails.</td>
</tr>
</tbody>
</table>

**NICEVALUE** The nicevalue defines an offset of the priority used to calculate the priorities of the child and its children. Values between -100 and 100 are permitted.

**PRIORITY** The specified priority in a Child Definition overwrites the priority of the Child Scheduling Entity Definition. Values between 0 (high priority) and 100 (low priority) are permitted.

**TRANSLATION** Setting the Exit State Translation for a child results in the Exit State of the child being translated to an Exit State which is merged in the resultant Exit State of the Parent Submitted Entity.

If no translation is specified, a Child State that is not at the same time a valid Parent State is ignored.

If a translation has been specified, all the Child States have to translated to a valid Parent State.

**SUSPEND CLAUSE** The child suspend clause defines whether a new Submitted Job is suspended in the context of this Child Definition.

The table below shows the possible values and their meaning regarding the suspend clause:
**suspend clause**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>suspend  The child is suspended regardless of the value of the suspend flag specified in the Child Scheduling Entities.</td>
</tr>
<tr>
<td>nosuspend The child is not suspended regardless of the value of the suspend flag specified in the Child Scheduling Entities Definition.</td>
</tr>
<tr>
<td>childsuspend The child is suspended if the suspended flag has been set in the Child Scheduling Entity.</td>
</tr>
</tbody>
</table>

If **suspend** has been specified, a resume clause can optionally be given as well which triggers an automatic resume at the specified time or at the end of the specified interval.

The submit time is taken as the reference for partially qualified points in time. T16:00 means, therefore, that if the submit time 15:00 has been set, the job will start after about an hour. If the submit time is later than 16:00, however, the job will wait until the next day.

**DYNAMIC CLAUSE** The child dynamic clause defines whether the child is always automatically submitted by the system when the parent is submitted as well.

Dynamic children are used by Running Jobs in the context of Trigger Definitions and programmatic submits. To be able to submit a child, this child must be defined as a dynamic child.

The following table shows the possible values in the dynamic clause and their meanings.

<table>
<thead>
<tr>
<th>dynamic clause</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>static</td>
<td>The child is automatically submitted with the parent.</td>
</tr>
<tr>
<td>dynamic</td>
<td>The child is not automatically submitted with the parent.</td>
</tr>
</tbody>
</table>

Milestones use different semantics for their children. Whenever a Scheduling Entity is dynamically submitted in a Master Run that is also a child of a milestone in the same Master Run, the Submitted Scheduling Entity is bound to this milestone as a child. This means that a milestone can only be final if its dependencies have been fulfilled and all its children are final. In other words, a Milestone collects child instances that are dynamically submitted by other Submitted Entities and waits until these Submitted Entities have finished. For this to function correctly, a dependency of the Submitted Scheduling Entity should be defined.

**dependency mode** The dependency mode defines which Required Submitted Entities have to achieve a Final State before the dependent Submitted Entity can exit the ‘Dependency Wait’ System State.

The following table shows the possible Dependency Modes and their meanings.
User Commands

<table>
<thead>
<tr>
<th>dependency mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all</td>
<td>The Submitted Entity exits the Dependency Wait State after all the dependencies have been fulfilled.</td>
</tr>
<tr>
<td>any</td>
<td>The Submitted Entity exits the Dependency Wait State after at least one dependency has been fulfilled.</td>
</tr>
</tbody>
</table>

**environment** Each job has to define which environment is needed to execute the job. The job can only be executed by job servers that fulfil all the Static Resource requirements listed in the Environment Definition. The environment option only applies for jobs.

**errlog** The errlog option defines the file where error outputs (stderr) from the process to be executed are written. If the file name is relative, the file is created relative to the working directory of the job. This option is only valid for jobs.

**footprint** Footprints are sets of requirements for System Resources. If several jobs are defined with similar requirements, this is made that much easier by using footprints. The job can only be executed by job servers that fulfil all the Static Resource requirements listed in the Footprint Definition. The footprint option only applies for jobs.

**group** The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

**inherit grant** The inherit grants clause allows you to define which privileges are to be inherited through the hierarchy. If this clause is not specified, all privileges are inherited by default.

**kill program** This option is used to create the possibility for prematurely terminating running processes from within the Scheduling System. Usually, the kill program contains the PID of the Running Job as a parameter (e.g. `kill -9 $(PID)`).
For details about command line parsing, variants and parameter substitutions, refer to the “run program” option on page 114.
**logfile**  The logfile option defines the file where the standard output (stdout) from the process to be executed is written. If the file name is relative, the file is created relative to the working directory of the job. This option is only valid for jobs.

**mapping**  The mapping option defines the Exit State Mapping that is used to translate operating system Exit Codes of an executable program to an Exit State. If a job does not have a mapping, the default Exit State Mapping of the job's Exit State Profile is used. For a detailed description of the Exit State Mapping, refer to the "create exit state mapping" command on page 85.

**nicevalue**  The nicevalue option defines a correction that is used for the calculation of the priorities for the job and its children. Values between -100 and 100 are permitted.

**parameter**  The parameters section defines which parameters and input values are required by a job and how the job exchanges data with other jobs and the scheduling system. The parameters can be used in the specification of the Run program, Rerun program, Kill program, working directory, log file and error log file, as well as in triggers and Dependency Conditions. A job can also query or set parameters at runtime. Variables that have been defined at runtime and not by the job definition are only visible to the job itself and cannot be referenced. The same is also true, of course, for all variables that are defined as `local` as well as for the system variables mentioned below. Occasionally, however, it is necessary to make one or more of the (e.g.) system variables known externally. This can be easily done by means of a small trick. If the value of a parameter contains a character string in the form `$something` (i.e. the characters $ followed by a name), this is interpreted as being the name of a variable, and an attempt is made to resolve this variable in the scope of the object that delivered the original value for the parameter. This is how, for example, a job `SYSTEM.A` can define a constant called `MYJOBNAME` with `$JOBNAME` as its content. If the constant `MYJOBNAME` is now addressed from outside the system via a reference, the delivered result is the value `SYSTEM.A`. A number of system variables are always defined for each job. These are set by the system and can be read by the job.

These system variables are:
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JOBID</td>
<td>Submitted entity id for the job</td>
</tr>
<tr>
<td>MASTERID</td>
<td>Submitted entity id for the Master Job or Batch</td>
</tr>
<tr>
<td>KEY</td>
<td>&quot;Password&quot; of the job for connecting to the scheduling system as a job with &quot;JOBID&quot;</td>
</tr>
<tr>
<td>PID</td>
<td>The operating system process id of the job. This parameter is only set for Kill programs.</td>
</tr>
<tr>
<td>LOGFILE</td>
<td>Name of the log file (stdout)</td>
</tr>
<tr>
<td>ERRORLOG</td>
<td>Name of the error log file (stderr)</td>
</tr>
<tr>
<td>SDMSHOST</td>
<td>Host name of the scheduling server</td>
</tr>
<tr>
<td>SDMSPORT</td>
<td>Listen port of the scheduling server</td>

Table 6.1.: List of System Variables

The TRIGGER... system variables are only populated if the job was submitted by a trigger. For a more detailed description of the TRIGGER... system variables, refer to the create trigger statement on page 132.

When a job is executed, the parameters used in commands, workdir and file specifications are resolved conform to the sequence given below:

1. System variable
2. The job’s own address space
3. The address space of the job and submitting parents, from bottom to top
4. The address space of the job server executing the job
5. The address space of the parent scopes of the job server executing the job, from bottom to top
6. The job definition’s parent folders, from bottom to top
7. The parent folders of the parent jobs, from bottom to top

If the configuration parameter ‘ParameterHandling’ for the server has been set to ‘strict’ (default), accessing variables that are not defined in the job definition will trigger an error message unless it is a system variable.

If the contents of a variable includes a reference to another parameter, this parameter is evaluated and replaced in the context of the defining job.
User Commands

create job definition

The different parameter types and their semantics are described below:

**IMPORT** Import-type parameters are used to hand over the data for a Job Scheduling Environment to another job. This type is almost like the parameter type, although import type parameters cannot be handed over like parameters when a job is submitted. Import-type parameters can have a default value, which is used if no value can be acquired from the scheduling environment.

**PARAMETER** Parameter-type parameters are used to hand over the data from a Job Scheduling Environment to another job. This type is almost like the import type, but parameter-type parameters can be handed over as parameters when a job is submitted. Parameter-type parameters can have a default value, which is used if no value can be acquired from the scheduling environment.

**REFERENCE** Reference-type parameters are normally used to hand over results from one job to another. The fully qualified name of the job definition and the name of the referencing parameter are required to create a reference. The Submitted Entity with the closest match to the job definition of the reference is sought to resolve the reference. If this allocation cannot be made clearly enough, this triggers an error message. If a matching Submitted Entity could not be found, the default value (if defined) is returned.

**REFERENCE CHILD** Child Reference parameters are used to refer to the parameters of direct or indirect children. This can be useful for reporting purposes, for example. A Child Reference parameter is defined using a fully qualified job definition name together with the name of the parameter to be qualified. When resolving the parameter, the Submission Hierarchy is searched downwards instead of upwards as is the case with Reference Parameters. The behaviour for the resolution is otherwise identical to the resolution of Reference Parameters.

**REFERENCE RESOURCE** Resource Reference-type parameters are used to refer to parameters of allocated resources. This parameter type requires the fully qualified name of a Named Resource together with an additional parameter name to specify the default reference. The prerequisite for using a Resource Reference parameter is that the resource is also requested. The value is determined in the context of the allocated resource.

**RESULT** Result-type parameters can acquire a value from the job (using the API). As long as this value has not been set, the optional default value is returned when the value is queried.

**CONSTANT** Constant-type parameters are parameters that have a value specified in the definition. This value can therefore not change during runtime.

**LOCAL** These variables are only visible from the perspective of the defining job.

**priority** The priority of a job determines the order in which jobs are executed. Values between 0 (high priority) and 100 (low priority) are permitted. The priority
option only applies for jobs.

**profile**  The profile defines the Exit State Profile that describes the valid Exit State of the Scheduling Entity. For a detailed description of the Exit State Profile, refer to the “create exit state profile” command on page 86.

**required**  The ‘required’ section defines the dependencies of other submitted entities in a Master Run which must be fulfilled until the Submitted Entity is capable of carrying on running. Whether all the dependencies have to be fulfilled or just one of them is defined by the ‘dependency’ mode’. Dependencies are defined in a comma-separated list of fully qualified names of Scheduling Entities (including folder path names). Dependencies only apply between the Submitted Entities of the Master Run. Synchronizing Resources have to be used to synchronise the Submitted Entities from different Master Runs. After the Submitted Entity instances of the Submitted Scheduling Entity hierarchy have been created, the system searches for the dependencies as follows: Beginning with the parent of the dependent Submitted Entity, all the children are searched for an instance of the Required Scheduling Entity whereby the branch with the dependent Submitted Entity is obviously ignored. If no instance is found, the search continues in the Submit Hierarchy Parents until precisely one instance has been found. If an instance can still not be found, the property ‘unresolved’ defines how this situation is handled by the system. If more than one Submitted Entity is found, the submit fails with an ‘ambiguous dependency resolution’ error. During the execution of a Master Run, a Scheduling Entity can attain an ‘unreachable’ state because the dependencies can no longer be fulfilled. This can happen if a Required Scheduling Entity reaches a Final State that is not entered in the list of required states for dependencies or by cancelling a Submitted Entity that is required by another Submitted Entity. These two cases are handled differently. If the unreachable situation is caused by a Submitted Entity that finishes with an unsuitable Exit State, the system determines the Exit State Profile of the dependent Submitted Entity and sets the Exit State to the state that is marked as being ‘unreachable’ in the profile. If none of the Profile States is marked as an unreachable state or the unreachable state was caused by a Submitted Entity being cancelled, the dependent Submitted Entity is set to the unreachable state, which can only be resolved by an operator ignoring the dependency or cancelling the dependent entity. All the direct or indirect children of a job or batch inherit all the parent’s dependencies. This means that no child of a job or batch can exit the dependency wait state as long as the parent itself is in this state. Children of milestones do not inherit the dependencies from their parent.
The properties of the dependency definitions are described below:

**CONDITION** It is possible to stipulate a condition for a dependency. The dependency is only fulfilled if the evaluation of the condition returns the truth value “true”. If no condition is specified, the condition is always deemed to have been fulfilled.

**DEPENDENCY NAME** A name can be optionally specified for the dependency when defining a function. Children (both direct and indirect) can refer to the name in order to ignore this dependency.

**MODE** The mode property is only relevant if the required Scheduling Entity is a job with children. In this case, the Dependency Mode defines the time when the dependency is fulfilled.

The table below shows the possible values and their meanings.

<table>
<thead>
<tr>
<th>dependency mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all_final</td>
<td>The required job and all its children must have reached a Final State.</td>
</tr>
<tr>
<td>job_final</td>
<td>Only the required job itself has to reach a Final State, the state of the children is irrelevant.</td>
</tr>
</tbody>
</table>

**STATE** The state property of a dependency defines a list of Final States that the required Scheduling Entity can achieve to fulfil the dependency. Without this option, the dependency is fulfilled if the required Scheduling Entity reaches a Final State.

It is also possible to stipulate a condition for a state. If a condition has been specified, the dependency is only deemed to have been fulfilled if the condition is fulfilled as well. The syntactic rules for specifying conditions are the same as those that apply to triggers. For more details, refer to the create trigger statement on page 132. Several implicit definitions are also available as options:

- **default** — The dependency is fulfilled if the predecessor has reached one of the states that are defined in its profile as being a default dependency.

- **all reachable** — The dependency is fulfilled if the predecessor has reached one of the states that are not defined as being unreachable.

- **reachable** — The dependency is fulfilled if the predecessor has reached the state defined as being unreachable.

**UNRESOLVED** The unresolved property specifies how the system should handle a situation where no Submitted Entity instance could be found during a Submit Operation for a required Scheduling Entity.

The possible behavioural patterns are described in the table below:
create job definition

<table>
<thead>
<tr>
<th>unresolved</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>The submit operation fails with an error message</td>
</tr>
<tr>
<td>ignore</td>
<td>The dependency is tacitly ignored</td>
</tr>
<tr>
<td>suspend</td>
<td>The dependency is ignored, but the dependent Submitted Entity is placed in a 'suspended' state and requires a user action to continue</td>
</tr>
</tbody>
</table>

rerun program  If a rerun program command line has been defined for a job, this is executed instead of the run command line when the job is restarted after a failure. For details about command line parsing, variants and the substitution parameter, refer to the “run program” option on page 114.

resource  The “resource” section of a job definition defines resource requirements in addition to those requirements indirectly defined by the “environment” and “footprint” options.

If the same Named Resource as in the footprint is required here, the requirement in the Resource Section overwrites the requirement in the footprint.

Since environments only require Named Resources with the usage “static” and footprints only require Named Resources with the usage “system”, the Resource Section in a job definition is the only place where resource requirements for Named Resources with the usage “synchronizing” can be defined.

Resource requirements are defined by the fully qualified path name to a Named Resource defined with the following additional requirement options:

- **AMOUNT** The amount option is only valid with requests for Named Resources of the type “System” or “Synchronizing”. The amount in a Resource Request expresses how many units of the Required Resource are allocated.

- **EXPIRED** The expired option is only valid for Synchronizing Resources with a defined Resource State Profile. If the expired option is specified, the time to which the Resource State of the resource has been set cannot be less recent than the time given by the expire option. A negative Expire value means that a resource must be at least as old as given here. The Resource State can only be set by the old resource command (see page 57) or automatically when defining a Resource State Mapping which converts the Exit State and Resource State into a new Resource State. Even if, in such a case, the new Resource State is the same as the old Resource State, the Resource State is considered to have been set.

- **LOCKMODE** The lockmode option in a resource requirement is only valid for Synchronizing Resources. Five possible lockmodes are defined:
<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>Exclusive lock</td>
</tr>
<tr>
<td>S</td>
<td>Shared lock</td>
</tr>
<tr>
<td>SX</td>
<td>Shared exclusive lock</td>
</tr>
<tr>
<td>SC</td>
<td>Shared compatible lock</td>
</tr>
<tr>
<td>N</td>
<td>Nolock</td>
</tr>
</tbody>
</table>

The important aspect here is the compatibility matrix:

<table>
<thead>
<tr>
<th></th>
<th>X</th>
<th>S</th>
<th>SX</th>
<th>SC</th>
<th>N</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>N</td>
<td>N</td>
<td>N</td>
<td>N</td>
<td>Y</td>
</tr>
<tr>
<td>S</td>
<td>N</td>
<td>Y</td>
<td>N</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>SX</td>
<td>N</td>
<td>N</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>SC</td>
<td>N</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>N</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
</tr>
</tbody>
</table>

The purpose of the exclusive lock is to have exclusive access to the resource to be able to set the Resource State and possibly parameter values. A common example of where the exclusive lock is used is when reloading a database table.

The purpose of the shared lock is to allow other users to use the resource in the same way while preventing them from making any changes. The most frequent scenario for using shared locks is for a large-scale ongoing reading of a database table. Other read processes can simply be tolerated, but no write transactions are allowed.

The purpose of the shared exclusive lock is to have a second shared lock which is not compatible with the normal shared lock. If we use the normal use shared lock for large read transactions, then we use the shared exclusive lock for small write transactions. Small write transactions can easily run in parallel, but if they create a large read transaction when doing so, they will almost certainly cause a “snapshot too old” or other similar problems.

The purpose of the shared compatible lock is to have a shared lock that is compatible with both the shared and exclusive locks. This lock type is intended for short read transactions which do not conflict with small write transactions or large read transactions. Small read transactions obviously don’t conflict with other small read transactions. Running small read and large write transactions in parallel may cause problems.

The purpose of the nolock is to ensure that the resource exists and that all the other properties of the resource cover requirements. The resource is not locked and anything can happen, including state changes.

**STATE** The state option is only valid for Synchronizing Resources with a Resource State Profile. It is used to specify valid Resource States for this job. A resource can only be allocated if it is in one of the required states.
STATE MAPPING The state mapping option is only valid for Synchronizing Resources that specify a Resource State Profile and are requested with an “exclusive” lock-mode. The mapping defines a function that maps the combinations of Exit States and Resource States in a new Resource State. For more detailed information about resource state mappings, refer to the create resource state mapping statement on page 123.

KEEP The keep option in a Resource Request defines the time when the resource is released. The keep option is valid for both System and Synchronizing Resources. There are three possible values. Their meanings are explained in the table below:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>nokeep</td>
<td>The resource is released at the end of the job. This is the default behaviour.</td>
</tr>
<tr>
<td>keep</td>
<td>The resource is released as soon as the job has reached the Final State.</td>
</tr>
<tr>
<td>keep final</td>
<td>The resource is released when the job and all its children are final.</td>
</tr>
</tbody>
</table>

STICKY The sticky option is only valid for Synchronizing Resources. If sticky is specified, the resource is allocated by the master batch (this is called a MASTER_RESERVATION) for as long as other jobs in the batch that require the “sticky” resource. The amount and lockmode for the Master Reservation are derived from all the sticky requirements of all the children. The amount is the maximum needed by any job. The lockmode is exclusive as long as at least two jobs exist which request the resource with a lockmode other than noLock. An exception is the combination of Shared and Shared Compatible lock requests. This combination results in lockmode Shared.

An attempt is made to fulfil all the requirements from the Master Reservation.

A name can be optionally assigned for the sticky allocation. As a basic principle, only those requests with the same name are taken into account for the previously described method. That’s why a master batch can have several MASTER_RESERVATIONS at the same time. Several separate critical regions can be realised within a sequence with the aid of the names.

A parent job or batch can be specified in addition to, or even instead of, the name. The corresponding instance of the parent is then determined at runtime from the submission hierarchy. The sticky request is only valid from the parent downwards. In principle, this can be interpreted as if the parent’s ID represents a part of the name of the sticky request. This mechanism allows separate critical regions to be easily implemented in dynamically submitted sub-workflows.

runtime The runtime option is used to define the estimated runtime of a job. This time can be valuated when activating triggers.
**User Commands**  
create job definition

**run program**  
The run program command line is mandatory for jobs because it specifies the command that is to be executed for this job.  
The command line is separated by whitespace characters in a command and a list of arguments. The first element in the command line is regarded as the name of the executable program that is to be run, and the rest are the parameters for the program.  
Whether the job server uses the PATH environment variable when searching for the executable file is a characteristic of the job server.  
System and job parameters can be addressed with $ Notation.  
Quoting can be used to forward whitespace characters and $ characters as part of the command line. The quoting complies with Unix Bourne shell rules. This means that double quotes prevent whitespace characters from being interpreted as separators. Single quotes also prevent variables from being resolved. Backticks can be used for quoting. The parts of the command line that have been quoted in backticks are regarded as having been single quoted, but the backticks remain a part of the argument. Other quotes are removed.

Example:

The run command line `sh -c ''example.sh ${JOBID} \$HOME'' '$SHELL'` will execute the program `sh` with the parameters `-c',`example.sh 4711 $HOME` and `$SHELL` (assuming that the Submitted Entity has the ID 4711).  
If the executable program (the first element of the command line) is a valid integer, the command line is not run by the job server. Instead, the job is treated as if it had completed itself with the integer as the Exit Code. Dummy jobs with `true` or `false` as the program can now be implemented as `0` instead of `true` or `1` instead of `false` and are therefore processed much more efficiently and quickly by the system.  
Should it really be necessary to run an executable with a number as the name, this can be achieved by using a path prefix (`./42` instead of `42`).

**suspend**  
The suspend option defines whether a Submitted Entity is suspended at the submit time.  
If the suspend option is specified, the resume clause can be optionally used. This can then trigger an automatic resume at or after the specified time.  
If the resume time is specified by the incomplete date format (see also page 6), the resume takes place at the first suitable time after the submit time.  
If a submit takes place at 16:00, for example, and T17:30 is entered as the resume time, the resume will take place on the same day at 17:30. But if T15:55 is specified as the resume time, the job will have to wait until the next day at 15:55.

**timeout**  
The timeout clause of a job definition defines the maximum time for which the job waits until its resource requirements are fulfilled.
When the timeout condition is reached, the job gets the Exit State specified in the timeout clause. This Exit State must be an element of the Exit State Profile. If no timeout option is given, the job will wait until all the requirements have been fulfilled.

**type**  The type option specifies the Scheduling Entity type that is being created or modified.

**workdir**  The workdir of a Scheduling Entity-type job defines the directory where the run, rerun or kill program is executed.

**master**  The master option defines whether this Scheduling Entity can be submitted in order to create a Master Run.

**Output**

This statement returns a confirmation of a successful operation.
create named resource

Purpose

The purpose of the create named resource statement is to define a class of resources.

Syntax

The syntax for the create named resource statement is

```
create [ or alter ] named resource resourcepath
with WITHITEM {, WITHITEM}
```

WITHITEM:

```
  group = groupname [ cascade ]
  | inherit grant = none
  | inherit grant = ( PRIVILEGE {, PRIVILEGE} )
  | parameter = none
  | parameter = ( PARAMETER {, PARAMETER} )
  | state profile = < none | rspname >
  | usage = RESOURCE_USAGE
```

PRIVILEGE:

```
  create content
  | drop
  | edit
  | execute
  | monitor
  | operate
  | resource
  | submit
  | use
  | view
```

PARAMETER:

```
  parametername constant = string
  | parametername local constant [ = string ]
  | parametername parameter [ = string ]
```

RESOURCE_USAGE:

```
```
create named resource

<table>
<thead>
<tr>
<th>category</th>
</tr>
</thead>
<tbody>
<tr>
<td>static</td>
</tr>
<tr>
<td>synchronizing</td>
</tr>
<tr>
<td>system</td>
</tr>
</tbody>
</table>

**Description**

The create named resource statement is used to define classes of resources. These classes define the name, the usage type and optionally the utilised Resource State Profile as well as the parameters.

**group** The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

**parameter** It may be useful to use its parameters in conjunction with allocating resources. For example, a resource like RESOURCE.TEMP_SPACE could have a parameter called LOCATION. This would allow a job to use a resource and allocate temporary storage space somewhere dependent upon the current instance of the Named Resource.

There are three types of parameters in a resource context:

<table>
<thead>
<tr>
<th>Typ</th>
<th>Bedeutung</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>constant</strong></td>
<td>This parameter type defines the value that is constant for all resources.</td>
</tr>
<tr>
<td><strong>local constant</strong></td>
<td>This parameter type defines a non-variable parameter whose value can deviate between instances of the same Named Resource.</td>
</tr>
<tr>
<td><strong>parameter</strong></td>
<td>The value of such a parameter can be changed by jobs that have exclusively locked this resource.</td>
</tr>
</tbody>
</table>

Table 6.2.: Named Resource parameter types

**state profile** A State Resource Profile can be specified in the case of Synchronizing Resources. This allows jobs to request the resource in a particular state. Resource State changes can be used to activate triggers.

**usage** The usage of the Named Resource can be one of the following:
User Commands

create named resource

<table>
<thead>
<tr>
<th>Usage</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Categories behave like folders and can be used to arrange the Named Resources in a clearly organised hierarchy.</td>
</tr>
<tr>
<td>static</td>
<td>Static resources are resources which, if requested, must be present in the scope in which the job is running but which cannot be used up. Possible examples of Static Resources are a particular operating system, shared libraries for DBMS access operations or the presence of a C compiler.</td>
</tr>
<tr>
<td>system</td>
<td>System Resources are resources that can be counted. Possible examples are the number of processes, the capacity of the temporary memory or the availability of (a number of) tape drives.</td>
</tr>
<tr>
<td>synchronizing</td>
<td>Synchronizing Resources are the most complex resources and are used to synchronise multiple access operations. One possible example is a database table. Multiple access operations may be tolerated or not depending on the type of access (large read transactions, large write transactions, multiple small write transactions, etc.).</td>
</tr>
<tr>
<td>pool</td>
<td>pool-type Named Resources are used to create so-called Resource Pools. These pools allow the distribution of amounts for System Resources to be regulated centrally and flexibly.</td>
</tr>
</tbody>
</table>

Table 6.3.: Named Resource usage

factor  When creating a Named Resource, the factor by which the specified amounts in a resource request are multiplied can be specified. The default factor is 1. This factor can be overwritten for each instance of this Named Resource (i.e. for each resource).

inherit grant  The inherit grants clause allows you to define which privileges are to be inherited through the hierarchy. If this clause is not specified, all privileges are inherited by default.

Output

Output  This statement returns a confirmation of a successful operation
create resource

Purpose

The purpose of the create resource statement is to create an instance of a named resource within a scope, folder or job definition.

Syntax

The syntax for the create resource statement is

```
create [ or alter ] resource resourcepath in < serverpath | folderpath >
with WITHITEM {, WITHITEM}
```

WITHITEM:

```
amount = < infinite | integer >
| < online | offline >
| parameter = none
| parameter = (PARAMETER {, PARAMETER})
| requestable amount = < infinite | integer >
| state = statename
| touch [ = datetime ]
| group = groupname
```

PARAMETER:

```
parametername = < string | default >
```

Description

The create resource statement is used to instantiate Named Resources within scopes, folders or job definitions. In the latter case, only a template is created which is materialised as soon as the job is submitted and automatically destroyed as soon as the Master Run is Final or Cancelled. If the or alter option is specified, an existing resource is changed; otherwise, it is considered to be an error if the resource already exists.

**amount**  The amount clause defines the Available Amount for this resource. The amount option is not specified in the case of static resources.

**base multiplier**  The base multiplier is only relevant if the Resource Tracing is being used. The base multiplier determines the multiplication factor for trace base. If the trace base is designated as being $B$ and the trace multiplier as being $M$, 

<table>
<thead>
<tr>
<th>create resource</th>
<th>User Commands</th>
</tr>
</thead>
</table>

119
the mean allocation is determined for the periods $B \times M^0$, $B \times M^1$ and $B \times M^2$. The default value is 600 (10 minutes) so that the values for $B$, $10B$ and $100B$ (in minutes) are determined.

**factor** A Resource Factor has been implemented to allow resource requirements for jobs to be adjusted externally. This can be set in both the Named Resource and individually in the resource. Whether a job can be allocated a particular resource is determined by comparing the original request with the Requestable Amount. However, the actual allocation is taken from

$$\text{ceil}(\text{Requirement} \times \text{Factor})$$

**group** The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

**online** The online clause defines whether the resource is online or offline. A resource is not available if it is offline. This means that a job that requires this resource cannot run within this scope. But since the resource can be set to online, the job will wait and will not be set to an error state. This also applies to static resources.

**parameter** The parameter clause is used to set the values of the parameters that have been defined for the Named Resource. Parameters that are declared as a constant at Named Resource Level are not permitted here. All the other parameters can be specified, although this is not mandatory. If a parameter or a default value for this parameter has not been specified at Named Resource Level, the resolution returns an empty string. If parameter name = default is specified when changing the resource, the parameter takes on the default value analogue to the Named Resource. If the parameter is changed on the Named Resource level, this is visible on the Resource level for all the parameters that have been set to the default value. A number of system variables are always defined for each resource. These are set by the system and are available to jobs which allocate the resource for read access using "RESSOURCEREFERENCEs". These system variables are:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATE</td>
<td>The Resource State of a &quot;synchronizing&quot; resource with a state model</td>
</tr>
</tbody>
</table>

*Continued on next page*
**Continued from previous page**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMOUNT</td>
<td>The total amount of available resources</td>
</tr>
<tr>
<td>FREE_AMOUNT</td>
<td>The total amount of available free resources</td>
</tr>
<tr>
<td>REQUESTABLE_AMOUNT</td>
<td>The maximum amount that can be allocated by a job</td>
</tr>
<tr>
<td>REQUESTED_AMOUNT</td>
<td>The amount requested by the job</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>The touch timestamp of a &quot;synchronizing&quot; resource with a state model</td>
</tr>
</tbody>
</table>

Table 6.4.: List of System Variables

**requestable amount**  The *requestable amount* clause defines the amount of this resource that can be requested by a single job. This does not have to be the same as the available amount. If the requested amount is smaller than the amount, it is certain that a job cannot allocate all the available resources. If the Requestable Amount is greater than the amount, jobs can request more than the available amount without triggering a "cannot run in any scope" error. If the Requestable Amount is not specified, it is the same as the amount. The requestable amount option is not specified in the case of static resources.

**state**  The *state* clause defines the resource's state. This option is only valid for Synchronizing Resources with a Resource State Profile.

**tag**  To facilitate evaluating the trace table, resources and pools can now be marked with a tag. This tag should be unique within the resources and pools (i.e. the use of a tag for both a resource and a pool is prohibited as well).

**touch**  The *touch* clause defines the last time when the status of the resource (of a job) was changed. This timestamp is not set if a Resource State has been set manually. This option is only valid for Synchronizing Resources with a Resource State Profile.

**trace base**  Tracing is deactivated if the trace base is *none*. Otherwise it is the basis for the valuation period.

**trace interval**  The trace interval is the minimum time in seconds between when Trace Records are written. Tracing is deactivated if the trace interval is *none*.

**Output**

This statement returns a confirmation of a successful operation.
create resource state definition

Purpose

The purpose of the create resource state definition statement is to create a symbolic name for a state of a resource.

Syntax

The syntax for the create resource state definition statement is

create [ or alter ] resource state definition statename

Description

The create resource state definition statement is used to define a symbolic name for a Resource State. The optional keyword or alter is used to prevent error messages from being triggered and the current transaction from being aborted if a Resource State Definition already exists. If it is not specified, the existence of a Resource State Definition with the specified name will trigger an error.

Output

This statement returns a confirmation of a successful operation

Example

A number of names for Resource States are defined in these examples.

create resource state definition empty;
create resource state definition valid;
create resource state definition invalid;
create resource state definition stage1;
create resource state definition stage2;
create resource state definition stage3;
create resource state mapping

Purpose

The purpose of the create resource state mapping statement is to define a mapping between the exit states of a job and the resulting resource state of a resource.

Syntax

The syntax for the create resource state mapping statement is

```
create [ or alter ] resource state mapping mappingname
with map = ( WITHITEM {, WITHITEM } )
```

WITHITEM:

```
statename maps < statename | any > to statename
```

Description

The create resource state mapping statement defines the mapping of Exit States in combination with Resource States to create new Resource States. The first state name must be an Exit State. The second and third state have to each be a Resource State. If a job terminates with the given Exit State, the resource state is set to the new state if the current state matches the first named state. If any is specified as the initial state, any Resource State is mapped to the new one. If both a specific mapping and a general mapping have been specified, the specific mapping has the highest priority.

Output

This statement returns a confirmation of a successful operation

Example

create resource state mapping
User Commands

create resource state profile

**create resource state profile**

**Purpose**

*Purpose* The purpose of the create resource state profile statement is to create a set of valid resource states.

**Syntax**

*Syntax* The syntax for the create resource state profile statement is

```
create [ or alter ] resource state profile profilename
with WITHITEM {, WITHITEM}

WITHITEM:
    initial state = statename
| state = ( statename {, statename} )
```

**Description**

*Description* The create resource state profile statement is used to define a set of valid Resource States for a (Named) Resource.

*state* The *state* clause defines which Resource State Definitions are valid within this profile.

*initial state* The initial state clause determines the initial state of a resource with this profile. The initial state does not have to be present in the list of states from the *state* clause. This allows a resource to be created without it immediately playing an active role in the system.

**Output**

*Output* This statement returns a confirmation of a successful operation

**Example**

*Example* In this example, the Exit State is to become invalid if it is empty.

```
create resource state profile example1
with
    state = (empty);
```
create schedule

Purpose

The purpose of the create schedule statement is to create an active container for scheduled events.

Syntax

The syntax for the create schedule statement is

```
create [ or alter ] schedule schedulepath [ with WITHITEM {, WITHITEM} ]
```

WITHITEM:

```
  < active | inactive >
  | inherit grant = none
  | inherit grant = ( PRIVILEGE {, PRIVILEGE} )
  | interval = < none | intervalname >
  | time zone = string
  | group = groupname
```

PRIVILEGE:

```
  create content
  | drop
  | edit
  | execute
  | monitor
  | operate
  | resource
  | submit
  | use
  | view
```

Description

With the create schedule statement, complex schedules can be created for jobs and batches using simple definitions.

active The active option causes the schedule to always trigger events in step with the specified interval (assuming that any events have been defined). The inactive option, on the other hand, prevents the schedule from triggering events in step with the specified interval. A hierarchical arrangement of schedules thus allows exception periods (such as downtimes) to be defined, for example.
User Commands  create schedule

**Group**  The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

**Interval**  The given interval acts as a ‘clock’ for the schedule. If an event is linked to the schedule, this event is triggered in rhythm with the interval.

**inherit grant**  The **inherit grants** clause allows you to define which privileges are to be inherited through the hierarchy. If this clause is not specified, all privileges are inherited by default.

**Output**

*Output*  This statement returns a confirmation of a successful operation.
create scheduled event

Purpose

The purpose of the create scheduled event is to define a connection between a schedule and an event.

Syntax

The syntax for the create scheduled event statement is

```plaintext
create [ or alter ] scheduled event schedulepath . eventname [ with
WITHITEM {, WITHITEM} ]
```

WITHITEM:

```plaintext
< active | inactive >
| backlog handling = < last | all | none >
| calendar = < active | inactive >
| horizon = < none | integer >
| suspend limit = < default | period >
| group = groupname
```

Description

Scheduled Events represent a link between events (what is to be done) and schedules (when should it be done).

cw backlog handling  The backlog handling function indicates how events that happened during a server downtime are to be handled. The three possible actions are shown in the table below:

<table>
<thead>
<tr>
<th>Action</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>last</td>
<td>Only the last event is triggered</td>
</tr>
<tr>
<td>all</td>
<td>All the events that happened in the meantime are triggered</td>
</tr>
<tr>
<td>none</td>
<td>None of the events that happened in the meantime are triggered</td>
</tr>
</tbody>
</table>

Group  The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

active  Scheduled Events can be marked as being active or inactive. If they are marked as being active, events are triggered. Correspondingly, events are not triggered if the Scheduled Event is marked as being inactive. This option can be used to deactivate Scheduled Events without the definition being lost.
User Commands

create scheduled event

**suspend limit**  The suspend limit defines the length of the delay before a job belonging to an event is automatically submitted with the suspend option. A delay can arise if, for whatever reason, the Scheduling Server goes offline. After the server has booted up again, events that have happened during the downtime are triggered dependent upon the **backlog handling** option. This means that the execution time is later than the scheduled execution time.

**Output**

*Output*  This statement returns a confirmation of a successful operation
create scope

Purpose

The purpose of the create scope statement is to create a scope within the scope hierarchy.

Syntax

The syntax for the create scope statement is

\[
create \ [ \text{or alter} \] < \text{scope serverpath} \mid \text{job server serverpath} > \ [ \text{with} \]
\]

\[
\text{JS\_WITHITEM} \{, \text{JS\_WITHITEM}\}
\]

PARAMETERITEM:

  parametername = dynamic
  parametername = < string | number >

PARAMETERSPEC:

  parametername = < string | number >

Description

Description

The create scope command is used to define a scope or job server and its properties.

Config

The config option allows a job server to be configured using key/value pairs.
The configuration is inherited downwards so that general configuration parameters can be set at scope level. This means that they are valid for all the job servers created below this level provided that the parameters at the lower level are not overwritten. When the job server logs onto the scheduling server, the server is given the list with the configuration parameters.

Enable

The enable option allows the job server to connect to the repository server. This option is not valid for scopes and is tacitly ignored if it is specified.

Disable

The disable option forbids the job server from connecting to the repository server. This option is not valid for scopes and is tacitly ignored if it is specified.

Group

The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

Node

The node specifies the computer on which the job server is running. This field has a purely documentary character.

Parameter

Parameters can be used for communication and data transfer purposes between jobs. They are available for use with the jobs and programs that are executed within the jobs. The parameters of scopes and job servers can be used to specify information about a job's runtime environment.
A Dynamic Parameter is fulfilled after the job server has logged on from within its own process environment. If the process environment of a job server is changed, attention has to be paid to this Dynamic Variable because otherwise race conditions can easily arise.

**Password**  The password option is used to set the password for the job server. This option is not valid for scopes and is tacitly ignored if it is specified.

**Output**

This statement returns a confirmation of a successful operation
User Commands

create trigger

create trigger

Purpose

The purpose of the create trigger statement is to create an object which submits a job dynamically when a certain condition is met.

Syntax

The syntax for the create trigger statement is

```
create [ or alter ] trigger triggername on CT_OBJECT [ < noinverse | inverse > ]
with WITHITEM {, WITHITEM}
```

**CT_OBJECT:**

```
job definition folderpath
```

**WITHITEM:**

```
< active | inactive >
| < nowarn | warn >
| limit state = < none | statename >
| < nomaster | master >
| rerun
| < noresume | resume in period | resume at datetime >
| state = none
| state = ( < statename {, statename} |
| CT_RSCSTATUSITEM {, CT_RSCSTATUSITEM} > )
| submit after folderpath
| submit folderpath
| submitcount = integer
| < nosuspend | suspend >
| [ type = ] CT_TRIGGERTYPE
| group = groupname
```

**CT_EVENT:**

```
< create | change | delete >
```

**CT_RSCSTATUSITEM:**

```
< statename any | statename statename | any statename >
```
create trigger  User Commands

CT_TRIGGERTYPE:
  before final
  | immediate local
  | immediate merge
  | warning

Description

The create trigger statement is used to create an object that waits for a certain event to happen following which a job or batch is submitted in response to this event.

If the or alter option is specified, an existing trigger is changed; otherwise, it is considered to be an error if the trigger already exists.

Triggers can be defined for Scheduling Entities or Synchronizing (Named) Resources. In the latter case, the trigger is evaluated every time the state of the resource or instance of the Named Resource changes. Resource Triggers are always so-called Master Triggers, i.e. they submit a new Master Batch or Master Job. Although triggers in Scheduling Entities can submit Master Batches, by default they submit new children. These children must be defined as (dynamic) children of the triggering Scheduling Entities.

active The active option enables the trigger to be activated or deactivated. This means that the trigger action can be temporarily suppressed without having to delete the trigger.

check The check option is only valid for until final and until finished triggers. It defines the time intervals between two evaluations of the conditions. The condition is always evaluated when a job finishes regardless of the defined intervals.

condition The condition option can be specified to define an additional condition which has to be checked before the trigger is activated. This condition is a Boolean expression and the trigger is activated if this condition returns 'true'.

Boolean operators Since this condition is a Boolean expression, Boolean operators can be used to create multiple complex conditions. This Boolean operators are:

- not (unary negation operator)
- and
- or
User Commands

create trigger

The usual priority rules apply. The ‘not’ operator takes priority over the ‘and’ operator, which in turn takes priority over the ‘or’ operator. Parentheses can be used to force a valuation sequence.
It is also permitted to use the Boolean constants false and true.

COMPARISON OPERATORS Comparisons can be used as part of Boolean expressions. The following comparison operators are defined.

• == (equal to)
• >= (greater than or equal to)
• <= (less than or equal to)
• != (not equal to)
• > (greater than)
• < (less than)
• =~ (pattern matches)
• !~ (pattern does not match)

All comparison operators can work with strings. With character strings, the ‘larger than’ and ‘less than’ operators use the ASCII value of the characters. The matching operators do not work with numbers.
For a full description of the regular expressions that can be used by the match operators, please refer to the original Java documentation for java.util.regex.

NUMERIC OPERATORS Since it cannot be guaranteed that decisions cannot only be made by comparing two values, the use of (numeric) operators is also permitted. The valid operators are:

• + (unary operator)
• – (unary negation operator)
• * (multiplication operator)
• / (division operator)
• % (modulo Operator)
• + (binary addition operator)
• – (binary subtraction operator)
LITERALS AND VARIABLES Literals are numbers (integers and floating point numbers) or character strings. Strings are delimited using double quotes ("). It is possible to use variables that are resolved within the context of the triggering job or resource. Variables are addressed by prefixing their name with a dollar sign ($). When a variable is resolved, it is initially assumed that it is a trigger variable. If this is not the case, it is interpreted as a job variable. This kind of resolution is often, but unfortunately not always, correct. The prefix job, trigger, or resource can be used to explicitly specify which object will initiate a search for the variable. Variables are usually created in uppercase. This can be prevented by quoting the name. However, the name is converted back to uppercase when addressing the variables in conditions. To avoid this, the name and prefix (where applicable) have to be written in braces.

The operands are interpreted as character strings or numbers depending upon the operator and the first operand. Multiplication, division, modulo and subtraction operations, as well as unary processes, are only defined for numeric values. The addition operator in a character string context causes the operands to be strung together.

FUNCTIONS Not everything can be simply expressed using (numeric) expressions, and so some additional functions have been added. The following functions are defined at this time:

- abs(expression) – the absolute value of the expression is returned
- int(expression) – the integer value of the expression is returned
- lowercase(expression) – the result of the expression is converted to lowercase and returned
- round(expression) – the expression is rounded and returned
- substr(source, from [, until]) – returns part of the character string source beginning at the position from up to the end of the string or, if until is specified, up to the position until
- str(expression) – the expression is returned without a space at the end
- uppercase(expression) – the result of the expression is converted to uppercase and returned

Functions can be nested in one another without any restrictions.

EXAMPLES To clarify this, here are some statements that specify the conditions. Since conditions are not just found in trigger definitions, some other examples are given here as well. However, the syntax is always the same. The first example shows a trigger that is activated when the job state changes to WARNING or FAILURE after it has already processed some rows ($NUM_ROWS > 0$).
CREATE OR ALTER TRIGGER ON_FAILURE 
ON JOB DEFINITION SYSTEM.EXAMPLES.E0100_TRIGGER.TRIGGER 
WITH 
  STATES = (FAILURE, WARNING),
  SUBMIT SYSTEM.EXAMPLES.E0100_TRIGGER.ON_FAILURE, 
  IMMEDIATE MERGE, 
  ACTIVE, 
  NOMASTER, 
  SUBMITCOUNT = 3, 
  NOWARN, 
  NOSUSPEND, 
  CONDITION = '$NUM_ROWS > 0';

The second example shows an environment that requires the value of the resource variable AVAILABLE to begin with a T (such as TRUE, True, true or Tricky).

CREATE ENVIRONMENT SERVER@LOCALHOST 
WITH RESOURCE = ( 
  RESOURCE.EXAMPLES.STATIC.NODE.LOCALHOST 
  CONDITION = '$RESOURCE.AVAILABLE =~ "[tT].*"', 
  RESOURCE.EXAMPLES.STATIC.USER.SERVER 
); 

The third example shows the same as the second one, except that here the parameter name is defined as being mixed case.

CREATE ENVIRONMENT SERVER@LOCALHOST 
WITH RESOURCE = ( 
  RESOURCE.EXAMPLES.STATIC.NODE.LOCALHOST 
  CONDITION = '${RESOURCE.Available} =~ "[tT].*"', 
  RESOURCE.EXAMPLES.STATIC.USER.SERVER 
); 

**event** The event option is only relevant for Object Monitor Triggers. It specifies for which types of events the trigger should be activated.

**group** The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

**main** The master option is used to define whether the job is submitted as a master or not. This option is only relevant for Job Triggers because Resource Triggers are always submitted as a master.

**master** The master option is used to define whether the job is submitted as a master or not. This option is only relevant for Job Triggers because Resource Triggers are always submitted as a master.
create trigger

User Commands

parent  The parent option is only relevant for Object Monitor Triggers. It can also only be specified in combination with the main option. If it is specified, a search is run for the corresponding job (or batch) within the tree submitted using the main job is sought and the trigger jobs are appended below the parent.

rerun  The rerun option can only react to restartable states and initiate an automatic rerun. In many cases, it will be practicable to also specify the suspend/resume options to allow a certain period of time between the resumes. Either the submit option or the rerun option have to be specified.

resume  The resume option can be used together with the suspend option to cause a delayed execution. There are two ways to do this. A delay can be achieved by specifying either the number of time units for the delay the time when the job or batch is to be activated.
If an incomplete time is defined, such as T16:00, the time for the trigger activation is taken as the reference time.

state  The state option is valid for all triggers apart from until final and until finished triggers. A list of Exit States can be specified for triggers that act on jobs. When the job in which the trigger is defined reaches an Exit State that is listed in the Trigger Definition, this activates the trigger (unless a condition has been specified that is valuated as false).
A list of state changes can be specified in the case of a trigger that acts on a (Named) resource. This allows each state change to be explicitly addressed. It is possible to activate a trigger when a state is exited by using the keyword any on the right. It is always possible to activate a trigger on reaching a certain state by specifying any on the left. The state option is omitted to activate a trigger after every state change.

submit  The submit option defines which job or batch is submitted when the trigger is activated.
Either the submit option or the rerun option have to be specified.

submitcount  The submitcount option is only permitted for triggers that act on jobs. It defines the number of times that a trigger can be activated. If this option is not specified, a submitcount of 1 is used.
If a submitcount of 0 is specified, the submitcount is set to the server parameter TriggerSoftLimit (the default value for this is 50). In the case of a rerun trigger, however, a submitcount of 0 means that there is no limit to the number of restart attempts.
If a submitcount greater than the TriggerSoftLimit is specified, the submitcount is restricted to the server parameter TriggerHardLimit (the default value for this is
This is done to avoid endless loops. The TriggerHardLimit can be set in the server configuration to $2^{31} - 1$ in order to virtually eliminate the restriction above.

**suspend**  The suspend option is used to submit the job or batch in a suspend state. This option is valid for all trigger types.

**type**  There are several types of triggers on jobs. The most important difference between them is the time at which they are checked. The table below shows a list of all the types with a brief description of their behaviour.

It must be emphasised that the type option is not valid for (named) resource triggers.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Check time</td>
</tr>
<tr>
<td>after final</td>
<td>Only after a final state is reached is a check run to establish whether the defined trigger has to be activated. If the trigger is not a Master Trigger, the newly submitted job will have the same parent as the triggering job. A special situation arises if the triggering job triggers its own submit. In this case, the newly submitted job replaces the triggering job. Since this exchange takes place before the dependency was checked, all the dependent jobs wait until the newly submitted job is final.</td>
</tr>
<tr>
<td>before final</td>
<td>Immediately before a final state is reached, a check is run to establish whether the defined trigger is to be activated. This is the last opportunity to submit new children. If this is done, the job or batch will not reach a Final State at this time.</td>
</tr>
<tr>
<td>finish child</td>
<td>A finish child trigger checks whether it is to be activated every time when a direct or indirect child finishes.</td>
</tr>
<tr>
<td>immediate local</td>
<td>The immediate local trigger local checks whether it has to be activated when a job is terminated. Only the Exit State of the job is taken into consideration.</td>
</tr>
</tbody>
</table>

### Table 6.5.: Description of the different types of triggers

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>immediate merge</td>
<td>The immediate merge trigger checks whether it has to be activated as soon as the Merged Exit State changes.</td>
</tr>
<tr>
<td>until final</td>
<td>The until final trigger periodically checks whether it has to be activated. This check starts as soon as a job or batch has been submitted and does not stop until it is final. The until final trigger imperatively requires a condition. This condition is checked at least once. This check takes place when the job or batch switches to the finished state.</td>
</tr>
<tr>
<td>until finished</td>
<td>The until finished trigger is similar to the final trigger. The only difference is that the until finished trigger stops the check as soon as the job is finished. The until finished trigger imperatively requires a condition. This condition is checked at least once. This check takes place when the job or batch switches to the finished state.</td>
</tr>
</tbody>
</table>

**Output**

This statement returns a confirmation of a successful operation
User Commands

**create user**

**Purpose**

The purpose of the `create user` statement is to create a pair of values which can be used to authenticate oneself to the server.

**Syntax**

The syntax for the `create user` statement is

```
create [ or alter ] user username
with WITHITEM {, WITHITEM}
```

**Description**

The `create user` statement is used to create a user. If "or alter" is specified, an already existing user is changed. Otherwise, an existing user will trigger an error.

The `default group` clause is used to specify the Default Group.

The `default group` clause defines the group that is used as the owner for all its objects created by the user if an explicit group was not specified when the object was created. The default group must be one of the user’s groups.

The `enable` option allows the user to connect to the repository server.

The `disable` option forbids the user from connecting to the repository server.

The `group` clause is used to specify the groups to which the user belongs. Every user is a member of the Public system group.

The `password` option is used to set the password for the user.
create user | User Commands

**rawpassword**  The rawpassword is used to set the user’s password that is required to connect to the repository server. The rawpassword is the already encrypted password. The rawpassword option has been implemented to be able to dump and restore users.

**Output**

This statement returns a confirmation of a successful operation.
7. deregister commands
**deregister**

**Purpose**

The purpose of the deregister statement is to notify the server that the jobserver is not to process jobs anymore. See also the register statement on page 238.

**Syntax**

The syntax for the deregister statement is

\[
\text{deregister serverpath . servername}
\]

**Description**

The deregister statement is used to notify the server about a more or less permanent failure of a job server. This message prompts different server actions. Firstly, all the running jobs on the job server (i.e. jobs in the state **started**, **running**, **to_kill** and **killed**) are set to the state **broken_finished**. Jobs in the state **starting** are reset to **runnable**. The job server is then removed from the list of job servers that are able to process jobs so that this job server is consequently no longer allocated any more jobs. A side effect of this is that jobs that can only run on this server due to their resource requirements are set to the state **error** with the message "Cannot run in any scope because of resource shortage". Finally, a complete reschedule is executed so that jobs are redistributed among the job servers. The job server is added to the list of job-processing job servers again by re-registering it (refer to the register statement on page 238).

**Output**

This statement returns a confirmation of a successful operation.
8. disconnect commands
User Commands  disconnect

**disconnect**

**Purpose**

*Purpose* The purpose of the disconnect statement is to terminate the server connection.

**Syntax**

*Syntax* The syntax for the disconnect statement is

    disconnect

**Description**

*Description* The connection to the server can be shut down using the disconnect statement.

**Output**

*Output* This statement returns a confirmation of a successful operation
9. drop commands
**drop comment**

**Purpose**

The purpose of the drop comment statement is to remove the comment.

**Syntax**

The syntax for the drop comment statement is

```
drop [ existing ] comment on OBJECTURL
```

**OBJECTURL:**

- `distribution distributionname for pool resourcepath in serverpath`
- `environment environmentname`
- `exit state definition statename`
- `exit state mapping mappingname`
- `exit state profile profilename`
- `event eventname`
- `resource resourcepath in folderpath`
- `folder folderpath`
- `footprint footprintname`
- `group groupname`
- `interval intervalname`
- `job definition folderpath`
- `job jobid`
- `named resource resourcepath`
- `parameter parametername of PARAM_LOC`
- `resource state definition statename`
- `resource state mapping mappingname`
- `resource state profile profilename`
- `scheduled event schedulepath . eventname`
- `schedule schedulepath`
- `resource resourcepath in serverpath`
- `< scope serverpath | job server serverpath >`
- `trigger triggeringname on TRIGGEROBJECT [ < noinverse | inverse > ]`
- `user username`

**PARAM_LOC:**

- `folder folderpath`
- `job definition folderpath`
- `< scope serverpath | job server serverpath >`
**Description**

The `drop comment` statement deletes the existing comment for the specified object. If the `existing` keyword is not specified, the absence of a comment is considered to be an error.

**Output**

This statement returns a confirmation of a successful operation.
User Commands

drop environment

drop environment

Purpose

Purpose  The purpose of the drop environment statement is to remove the specified environment.

Syntax

Syntax  The syntax for the drop environment statement is

\[ \text{drop [ existing | environment } \text{environmentname} \]

Description

Description  The drop environment statement is used to delete a definition from an environment. An error is triggered if jobs are still using this environment. If the \text{existing} keyword is being used, it is not considered to be an error if the specified environment does not exist.

Output

Output  This statement returns a confirmation of a successful operation
drop event

Purpose

The purpose of the drop event statement is to remove the specified event.

Syntax

The syntax for the drop event statement is

\[ \text{drop [existing] event eventname} \]

Description

The drop event statement is used to delete a definition of an event. If the existing keyword is being used, it is not considered to be an error if the specified event does not exist. An event cannot be deleted if Scheduled Events belong to it.

Output

This statement returns a confirmation of a successful operation
User Commands  drop exit state definition

**drop exit state definition**

**Purpose**

*Purpose*  The purpose of the drop exit state definition statement is to remove the specified exit state definition.

**Syntax**

*Syntax*  The syntax for the drop exit state definition statement is

\[\text{drop} \ [\text{existing}] \ \text{exit state definition} \ \text{statename}\]

**Description**

*Description*  The drop exit state definition statement is used to delete an Exit State Definition. It is considered to be an error if Exit State Profiles are still using this Exit State Definition. If the *existing* keyword is being used, it is not considered to be an error if the specified Exit State Definition does not exist.

**Output**

*Output*  This statement returns a confirmation of a successful operation.
drop exit state mapping

Purpose

The purpose of the drop exist state mapping statement is to remove the specified mapping.

Syntax

The syntax for the drop exit state mapping statement is

\[\text{drop} \ [\text{existing}] \ \text{exit state mapping} \ \text{mappingname}\]

Description

The drop exit state mapping statement is used to delete an Exit State Mapping. It is considered to be an error if jobs or Exit State Profiles are still using this Exit State Mapping. If the \text{existing} keyword is being used, it is not considered to be an error if the specified Exit State Mapping does not exist.

Output

This statement returns a confirmation of a successful operation
drop exit state profile

Purpose

The purpose of the drop exit state profile statement is to remove the specified profile.

Syntax

The syntax for the drop exit state profile statement is

```
drop [existing] exit state profile profilename
```

Description

The drop exit state profile statement is used to delete a definition of an Exit State Profile. It is considered to be an error if jobs are still using this Exit State Profile. If the `existing` keyword is being used, it is not considered to be an error if the specified Exit State Profile does not exist.

Output

This statement returns a confirmation of a successful operation
**drop folder**

**Purpose**

The purpose of the drop folder statement is to remove a folder and its contents from the system.

**Syntax**

The syntax for the drop folder statement is

```
drop [existing] FOLDER_OR_JOB {, FOLDER_OR_JOB} [cascade] [force]
```

**Description**

The drop folder statement removes folders and their contents from the system. There are two options:

- **Cascade** The cascade option deletes folders, job definitions and subfolders, but only if they are not referenced to the job definitions, for example as required job.

- **Force** With the force option, references to job definitions are removed as well. Force implies cascade. Folders cannot be deleted if they are not empty unless cascade or force has been specified.

**Output**

This statement returns a confirmation of a successful operation.
drop footprint

Purpose

Purpose  The purpose of the drop footprint statement is to remove the specified footprint.

Syntax

Syntax  The syntax for the drop footprint statement is

    drop [ existing ] footprint footprintname

Description

Description  The drop footprint statement is used to delete footprints and resource requirements. If the existing keyword is being used, it is not considered to be an error if the specified footprint does not exist.

Output

Output  This statement returns a confirmation of a successful operation
The purpose of the drop group statement is to remove a group from the system.

The syntax for the drop group statement is 

\[ \text{drop} [ \text{existing} ] \text{ group } \text{groupname} \]

The drop group statement is used to delete a group. If there are still any group members in this group, their membership is automatically terminated.

It is considered to be an error if the group is still the owner of an object.

It is not possible to delete a group that is defined as the Default Group for a user.

If the \text{existing} keyword is being used, it is not considered to be an error if the specified group does not exist.

This statement returns a confirmation of a successful operation.
drop interval

Purpose

Purpose The purpose of the drop interval statement is to remove the specified interval.

Syntax

Syntax The syntax for the drop interval statement is

\[ \text{drop [existing | interval } intervalname \text{] } \]

Description

Description The drop interval statement is used to delete intervals. If the \textit{existing} keyword is being used, it is not considered to be an error if the specified interval does not exist.

Output

Output This statement returns a confirmation of a successful operation.
drop job definition

Purpose

The purpose of the drop job definition statement is to remove the specified scheduling entity object.

Syntax

The syntax for the drop job definition statement is

\[\text{drop [existing] job definition folderpath . jobname [force]}\]

Description

The drop job definition statement deletes the given job definition.

If a job definition is referenced (for instance as Required Job), it cannot be deleted unless the force option is specified. If the force option is being used, all references to a job definition are also deleted.

Output

This statement returns a confirmation of a successful operation
drop named resource

Purpose

Purpose

The purpose of the drop named resource statement is to delete a class of resources.

Syntax

Syntax

The syntax for the drop named resource statement is

\[
\text{drop \ [existing] \ named resource \ resourcepath \ [cascade]}
\]

Description

Description

The drop named resource statement is used to delete Named Resources. It is considered to be an error if the Named Resource is still instantiated in scopes, job definitions and/or folders and the `cascade` option is not specified.

On the other hand, Scope Resources as well as folders and Job Definition Resources are deleted if the `cascade` option is specified.

If any requirements exist for the Named Resources that are to be deleted, the statement will fail.

If the `existing` keyword is being used, it is not considered to be an error if the specified Name Resource does not exist.

Output

Output

This statement returns a confirmation of a successful operation.
drop resource

Purpose

The purpose of the drop resource statement is to remove an instance of a named resource from a scope, folder or job definition.

Syntax

The syntax for the drop resource statement is

```
drop [existing] RESOURCE_URL [force]
```

```
RESOURCE_URL:
  resource resourcepath in folderpath
  | resource resourcepath in serverpath
```

Description

The drop resource statement is used to delete a resource. It is considered to be an error if the resource is still being allocated by Running Jobs. If the `existing` keyword is being used, it is not considered to be an error if the specified resource does not exist.

Output

This statement returns a confirmation of a successful operation.
drop resource state definition

Purpose

Purpose The purpose of the drop resource state definition statement is to remove the definition.

Syntax

Syntax The syntax for the drop resource state definition statement is

\[\text{drop} \ [\text{existing}] \ \text{resource state definition} \ \text{statename}\]

Description

Description The drop resource state definition statement is used to delete Resource State Definitions. It is considered to be an error if Resource State Profiles are still using this Resource State Definition. If the existing keyword is being used, it is not considered to be an error if the specified Resource State Definition does not exist.

Output

Output This statement returns a confirmation of a successful operation
drop resource state mapping

Purpose
The purpose of the drop resource state mapping statement is to delete the mapping.

Syntax
The syntax for the drop resource state mapping statement is

```
  drop [ existing ] resource state mapping mappingname
```

Description
The drop resource state mapping statement is used to delete a Resource State Mapping. It is considered to be an error if job definitions are using this Resource State Mapping. If the `existing` keyword is being used, it is not considered to be an error if the specified Resource State Mapping does not exist.

Output
This statement returns a confirmation of a successful operation
drop resource state profile

Purpose

The purpose of the drop resource state profile statement is to remove a resource state profile.

Syntax

The syntax for the drop resource state profile statement is

\[\text{drop } [\text{existing }] \text{ resource state profile profilename}\]

Description

The drop resource state profile statement is used to delete the definition of a Resource State Profile. It is considered to be an error if Named Resources are still using this Resource State Profile. If the \text{existing} keyword is being used, it is not considered to be an error if the specified Resource State Profile does not exist.

Output

This statement returns a confirmation of a successful operation.
**drop schedule**

**Purpose**

The purpose of the drop schedule statement is to remove the specified schedule.

**Syntax**

The syntax for the drop schedule statement is

```
 drop [ existing ] schedule schedulepath
```

**Description**

The drop schedule statement is used to delete schedules. If the `existing` keyword is being used, it is not considered to be an error if the specified schedule does not exist.

A schedule cannot be deleted if it has a Scheduled Event that belongs to it. It cannot be deleted either if child objects exist.

**Output**

This statement returns a confirmation of a successful operation
drop scheduled event

Purpose

Purpose The purpose of the drop scheduled event is to remove the specified scheduled event.

Syntax

Syntax The syntax for the drop scheduled event statement is

\[ \text{drop [ existing] scheduled event schedulepath . eventname} \]

Description

Description The drop interval statement is used to delete Scheduled Events. If the existing keyword is being used, it is not considered to be an error if the specified Schedule Event does not exist.

Output

Output This statement returns a confirmation of a successful operation
drop scope

Purpose

The purpose of the drop scope statement is to remove a scope and its contents from the scope hierarchy.

Syntax

The syntax for the drop scope statement is:

```
drop [ existing ] < scope serverpath | job server serverpath > [ cascade ]
```

Description

This statement is synonymous to the drop job server statement. The cascade option deletes the scope together with its contents.

Output

This statement returns a confirmation of a successful operation.
drop trigger

Purpose
The purpose of the drop trigger statement is to remove the specified trigger.

Syntax
The syntax for the drop trigger statement is

```
drop [ existing | trigger triggername on TRIGGEROBJECT [ < noinverse | inverse > ]
```

TRIGGEROBJECT:
- resource resourcepath in folderpath
- job definition folderpath
- object monitor objecttypename
- resource resourcepath in serverpath

Description
The drop trigger statement is used to delete a trigger.
If the existing keyword is being used, it is not considered to be an error if the specified trigger does not exist.

Output
This statement returns a confirmation of a successful operation
drop user

Purpose
The purpose of the drop user statement is to remove the user from the system.

Syntax
The syntax for the drop user statement is

\[ \text{drop \ [existing \] user username} \]

Description
The drop user statement is used to logically delete a user. If the \textit{existing} keyword is being used, it is not considered to be an error if the specified user does not exist.

Output
This statement returns a confirmation of a successful operation.
10. finish commands
User Commands finish job

finish job

Purpose

Purpose  The purpose of the finish job command is to inform the server about the termination of a job.

Syntax

Syntax  The syntax for the finish job statement is

\[
\text{finish job jobid} \\
\text{with exit code} = \text{signed_integer}
\]

\[
\text{finish job} \\
\text{with exit code} = \text{signed_integer}
\]

Description

Description  The finish job command is used by the job server to report the Exit Code for a process to the server. During the course of repair work, it may be necessary for an administrator to tell the server in this way that a job has terminated. Jobs can themselves report that they have finished. To do this, they connect to the server and use the second form of the statement.

Output

Output  This statement returns a confirmation of a successful operation
11. get commands
**get parameter**

**Purpose**

The purpose of the get parameter statement is to get the value of the specified parameter within the context of the requesting job, respectively the specified job.

**Syntax**

The syntax for the get parameter statement is

\[ \text{get parameter } \text{parametername} \quad [ \quad < \text{strict} \quad | \quad \text{warn} \quad | \quad \text{liberal} \quad > \quad ] \]

\[ \text{get parameter of } \text{jobid parametername} \quad [ \quad < \text{strict} \quad | \quad \text{warn} \quad | \quad \text{liberal} \quad > \quad ] \]

**Description**

The get parameter statement is used to get the value of the specified parameter within the context of a job.

The additional option has the following meaning:

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>strict</td>
<td>The server returns an error if the requested parameter is not explicitly declared in the job definition.</td>
</tr>
<tr>
<td>warn</td>
<td>A message is written to the server’s log file when an attempt is made to determine the value of an undeclared parameter.</td>
</tr>
<tr>
<td>liberal</td>
<td>An attempt to query an undeclared parameter is tacitly allowed. The default behaviour depends on the configuration of the server.</td>
</tr>
</tbody>
</table>

**Output**

This statement returns an output structure of type record.

**Main output description**

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE</td>
<td>Value of the requested parameter</td>
</tr>
</tbody>
</table>

Table 11.1.: Description of the output structure of the get parameter statement
get submittag

Purpose

The purpose of the get submittag statement is to get a (server local) unique identifier from the server. This identifier can be used to avoid race conditions between frontend and backend when submitting jobs.

Syntax

The syntax for the get submittag statement is

get submittag

Description

The get submittag statement is used to acquire an identification from the server. This prevents race conditions between the front end and back end when jobs are submitted. Such a situation arises when feedback about the submit does not reach the front end due to an error. By using a submittag, the front end can safely start a second attempt. The server recognises whether the job in question has already been submitted and responds accordingly. This reliably prevents the job from being submitted twice.

Output

This statement returns an output structure of type record.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE</td>
<td>The requested Submit Tag</td>
</tr>
</tbody>
</table>

12. kill commands
User Commands

**kill session**

**Purpose**

*Purpose*  The purpose of the kill session is to terminate the specified session.

**Syntax**

*Syntax*  The syntax for the kill session statement is

```
kill session sid
```

**Description**

*Description*  The list session command can be used to display a list of active sessions. The displayed session ID can be used to terminate the session in question with the kill session command. Only administrators (i.e. members of the Admin group) are allowed to use this statement. It is not possible to terminate your own session.

**Output**

*Output*  This statement returns a confirmation of a successful operation.
13. link commands
User Commands
link resource

link resource

Purpose

Purpose
The purpose of the link resource statement is to create a reference to a resource of another scope.

Syntax

Syntax
The syntax for the link resource statement is

```
link resource resourcepath in serverpath to < scope serverpath | job 
server serverpath > [ force ]
```

Description

Description
With the link resource statement it is possible to make the resource of another scope visible and usable in a scope. This is necessary if a logical process requires resources from more than one scope. This is very well the case, for example, with processes that communicate with a database system.

From the system’s perspective, it can scarcely differentiate between a Resource Link and the referenced resource. All operations such as allocating, locking, reading or setting variables take place on the base resource. This means that the link behaves as if it were the base resource. The only difference lies in the view of the allocations. With the base resource, all the allocations are shown. With a link, only those allocations that take place via the link are shown.

It is also possible to set links to links.

The force option can be used to overwrite an existing link. An already existing resource is deleted and the link is created. These operations are obviously only possible if the resource or link is not being used, i.e. if there are no allocations or reservations present.

Output

Output
This statement returns a confirmation of a successful operation.
14. list commands
list calendar

Purpose

The purpose of the list calendar statement is to get an overview of scheduled jobs.

Syntax

The syntax for the list calendar statement is

```
list calendar [ with LC_WITHITEM {, LC_WITHITEM} ]
```

```
LC_WITHITEM:
  endtime = datetime
  | filter = LC_FILTERTERM [or LC_FILTERTERM]
  | starttime = datetime
  | time zone = string
```

```
LC_FILTERTERM:
LC_FILTERITEM [and LC_FILTERITEM]
```

```
LC_FILTERITEM:
  ( LC_FILTERTERM [or LC_FILTERTERM] )
  | job . identifier < cmpop | like | not like > RVALUE
  | name like string
  | not ( LC_FILTERTERM [or LC_FILTERTERM] )
```

```
RVALUE:
  expr ( string )
  | number
  | string
```

Description

The list calendar statement gives you a list of all the calendar entries sorted by the start dates of the executable objects. If a period is specified, those objects whose start time plus the Expected Final Time lies in the selected period are also displayed.

Output

This statement returns a confirmation of a successful operation.
list dependency definition

Purpose

The purpose of the list dependency definition statement is to get a list of all dependencies of a job definition.

Syntax

The syntax for the list dependency definition statement is

```
list dependency definition folderpath
```

Description

The list dependency definition statement gives you a list of all the dependencies of a job definition.

Output

This statement returns an output structure of type table.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>
</tr>
<tr>
<td>SE_DEPENDENT_PATH</td>
<td>The folder containing the dependent Scheduling Entity.</td>

</tr>
</tbody>
</table>

Table 14.1.: Description of the output structure of the list dependency definition statement
list dependency hierarchy

Purpose

The purpose of the list dependency hierarchy statement is to get a list of all dependencies of a submitted entity.

Syntax

The syntax for the list dependency hierarchy statement is

```
list dependency hierarchy jobid [with EXPAND ]
```

EXPAND:

```
expand = none
|  expand = < ( id [, id] ) | all >
```

Description

The list dependency hierarchy statement gives you a list of all the dependencies of a Submitted Dependency.

**expand** The **expand** option can be used to make the hierarchy visible at children level. This is done by specifying in the list the IDs of the nodes whose children are to be made visible. If **none** is specified as an expand option, only the level below the requested node is made visible.

Output

This statement returns an output structure of type table.

**Main output description** The data items of the output are described in the table below.

<table>
<thead>
<tr>

Table 14.2.: Description of the output structure of the list dependency hierarchy statement
list environment

Purpose

The purpose of the list environment statement is to get a list of defined environments.

Syntax

The syntax for the list environment statement is

```
list environment
```

Description

The list environment statement is used to get a list of defined environments that are visible to the user.

Output

This statement returns an output structure of type table.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>

Table 14.7.: Description of the output structure of the list exit state profile statement
User Commands

list folder

list folder

Purpose

Purpose

The purpose of the list folder statement is to get a (partial) list of all folders defined in the system.

Syntax

Syntax

The syntax for the list folder statement is

```
list folder folderpath [ with WITHITEM {, WITHITEM} ]
```

WITHITEM:

```
expand = none
| expand = < ( id {, id} ) | all >
| FILTERTERM [or FILTERTERM]
```

FILTERTERM:

```
FILTERITEM [and FILTERITEM]
```

FILTERITEM:

```
( FILTERTERM [or FILTERTERM] )
| name like string
| not ( FILTERTERM [or FILTERTERM] )
| owner in ( groupname {, groupname} )
```

Description

Description

The list folder statement gives you a list for the specified folder with all the direct child folders.

expand

The `expand` option can be used to make the hierarchy visible at children level. This is done by specifying in the list the IDs of the nodes whose children are to be made visible. If `none` is specified as an expand option, only the level below the requested node is made visible.

filter

The child folders can be selected by name. Refer to the official Java documentation for the exact syntax used for regular expressions. The various conditions can be combined with one another using `and` and `or`. The usual valuation order of the operators applies (`and` before `or`).

194  |   list folder
Output

This statement returns an output structure of type table.

**Main output description**  The data items of the output are described in the table below.

<table>
<thead>

Table 14.11.: Description of the output structure of the list interval statement
**Purpose**

The purpose of the `list job` statement is to get a list of submitted entities based on the selection criteria specified.

**Syntax**

The syntax for the `list job` statement is

```
list job [ jobid [, jobid] ] [ with WITHITEM {, WITHITEM} ]
```

**WITHITEM:**

- `expand = none`
- `expand = < ( id {, id} ) | all >`
- `FILTERTERM { or FILTERTERM }`
- `mode = < list | tree >`
- `parameter = ( parametername {, parametername} )`

**FILTERTERM:**

```
FILTERITEM { and FILTERITEM }
```

**FILTERITEM:**

```
( FILTERTERM { or FILTERTERM } )
| < final | restartable | pending >
| exit state in ( statename {, statename} )
| < history | future > = period
| history between period and period
| job . identifier < cmpop | like | not like > RVALUE
| job in ( jobid {, jobid} )
| job server in ( serverpath {, serverpath} )
| job status in ( JOBSTATE {, JOBSTATE} )
| master
| master_id in ( jobid {, jobid} )
| merged exit state in ( statename {, statename} )
| name in ( folderpath {, folderpath} )
| name like string
| node in ( nodename {, nodename} )
| not ( FILTERTERM { or FILTERTERM } )
| owner in ( groupname {, groupname} )
| submitting user in ( groupname {, groupname} )
| warning
```
**User Commands**

**list job**

**RVALUE:**
- `expr (string)`
- `number`
- `string`

**JOBSTATE:**
- `broken active`
- `broken finished`
- `cancelled`
- `dependency wait`
- `error`
- `final`
- `finished`
- `killed`
- `resource wait`
- `Runnable`
- `running`
- `started`
- `starting`
- `submitted`
- `synchronize wait`
- `to kill`
- `unreachable`

**Description**

The list job statement gives you a list of Submitted Entities. The selection of the jobs can be finely specified as required that by defining a filter. Job parameter names can also be specified that are then visible in the output.

The statement `list job` without any further information is equivalent to the statement `list job with master` and therefore outputs the list of all the Master Jobs and Batches.

**expand** The expand option can be used to make the hierarchy visible at children level. This is done by specifying in the list the IDs of the nodes whose children are to be made visible. If `none` is specified as an expand option, only the level below the requested node is made visible.

**mode** `list` mode just outputs a list of selected jobs. If the `tree` mode is defined, however, all the parents for each selected job are outputted as well.

**parameter** Additional information about the selected jobs can be outputted by specifying parameter names. The parameters are valuated in the context of each job.
and the value of the parameter is displayed in the output. If this fails, the output is an empty string. This means that specifying non-existent parameter names does not have any adverse consequences. This allows state or progress details for jobs to be easily and clearly are displayed.

**filter** A large number of filters are available for filtering all the jobs present in the system. The individual filters can be combined with one another using Boolean operators. The usual order of priority operator applies here. The individual filter functions are briefly described here.

- **FINAL, RESTARTABLE, PENDING** This filter selects all the jobs in the state final respectively restartable or pending.

- **EXIT STATE** All jobs that are in an Exit State defined in the specified list are selected. This is the job’s own Exit State, and not the Merged Exit State which also takes the Exit States of the children into consideration.

- **HISTORY** By defining a history, only those jobs that have become final at the earliest before the given time are selected. All non-final jobs are selected.

- **FUTURE** Scheduled future jobs are also outputted by specifying a future. These events are determined based on Scheduled Events and calendar entries. “SCHEDULED” is outputted as the state of such jobs.

- **JOB.IDENTIFIER** This filter is used to select all those jobs whose defined parameters fulfil the condition. This allows all the jobs of a developer to be easily selected, for example. (This obviously assumes that each job has a parameter with the developer’s name).

  The **expr** Function can be used to perform calculations. The expression

  \[
  \text{job.starttime} < \text{expr}('\text{job.sysdate - job.expruntime * 1.5}')
  \]

  determines those jobs, that exceeded their expected runtime by more than 50%.

- **JOB IN (ID, ...)** This filter option is equivalent to specifying Jobids after “list job”. Only those jobs with one of the specified IDs are selected.

- **JOB SERVER** Only those jobs running on the specified job server are selected.

- **JOB STATE** This filter selects only those jobs that have one of the specified job states. For example, it is then easy to find all the jobs in the state broken_finished.

- **MASTER** Only the Master Jobs and Batches are selected.

- **MASTER>ID** Only jobs that belong to the specified Master Jobs and Batches are selected.

- **MERGED EXIT STATE** All jobs that are in a Merged Exit State defined in the specified list are selected. This is the Exit State that results from a job’s own Exit State in combination with the Exit States of the children.

- **NAME IN (FOLDERPATH, ...)** The jobs whose associated Scheduling Entity is included in the specified list are selected.
NAME LIKE STRING  The jobs whose associated Scheduling Entity has the matching name are selected. Refer to the official Java documentation for more details about the syntax used for regular expressions.

NODE  Jobs running on one of the specified nodes are selected. In this context, the node designates the entry for the node of the job server.

OWNER  Only the jobs of the defined owners (groups) are selected.

SUBMITTING USER  Only jobs that have been submitted by the specified user are selected.

Output

This statement returns an output structure of type table.

Main output description  The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>
</tr>
<tr>
<td>MASTER_ID</td>
<td>This is the ID of the Master Job.</td>
</tr>
<tr>
<td>HIERARCHY_PATH</td>
<td>The Hierarchy Path is the full path of the current entry. The single hierarchy levels are separated by a period.</td>
</tr>
<tr>
<td>SE_TYPE</td>
<td>This is the Scheduled Entity type.</td>
</tr>
<tr>
<td>PARENT_ID</td>
<td>This is the ID of the parent.</td>
</tr>
<tr>
<td>OWNER</td>
<td>The group owning the object</td>
</tr>
<tr>
<td>SCOPE</td>
<td>The scope or job server to which the job is allocated.</td>
</tr>
<tr>
<td>HTTPHOST</td>
<td>The host name of the scope for accessing log files via HTTP.</td>
</tr>
<tr>
<td>HTTPPORT</td>
<td>The HTTP port number of the job server for accessing log files via HTTP.</td>
</tr>
<tr>
<td>EXIT_CODE</td>
<td>The Exit Code of the executed process.</td>
</tr>
<tr>
<td>PID</td>
<td>The Pid is the process identification number of the monitoring job server process on the respective host system.</td>
</tr>
<tr>
<td>EXTPID</td>
<td>The Extpid is the process identification number of the utility process.</td>
</tr>
<tr>
<td>STATE</td>
<td>The State is the current state of the job.</td>
</tr>
<tr>
<td>IS_DISABLED</td>
<td>Indicates whether the submitted entity was submitted disabled.</td>
</tr>

Table 14.12.: Description of the output structure of the list job statement
list job definition hierarchy

Purpose

Purpose The purpose of the list job definition hierarchy statement is to get the complete jobtree of the specified job.

Syntax

Syntax The syntax for the list job definition hierarchy statement is

```
list job definition hierarchy folderpath [ with EXPAND ]
```

EXPAND:

```
expand = none
| expand = < ( id [, id] ) | all >
```

Description

Description The list job definition statement hierarchy gives you the complete tree structure of the specified job.

Output

Output This statement returns an output structure of type table.

Main output description The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>
</tr>
<tr>
<td>NAME</td>
<td>The object name</td>
</tr>
<tr>
<td>OWNER</td>
<td>The group owning the object</td>
</tr>
<tr>
<td>TYPE</td>
<td>This states the type of object. The following options are available: Batch, Milestone, Job and Folder.</td>
</tr>
<tr>
<td>RUN_PROGRAM</td>
<td>A command line that starts the script or program can be specified in the Run Program field.</td>
</tr>
<tr>
<td>RERUN_PROGRAM</td>
<td>The Rerun Program field specifies the command that is to be executed when repeating the job following an error (rerun).</td>
</tr>
</tbody>
</table>

</table>

Table 14.13.: Description of the output structure of the list job definition hierarchy statement
list named resource

Purpose

The purpose of the list named resource statement is to get a (partial) list of all defined named resources.

Syntax

The syntax for the list named resource statement is

```
list named resource [ resourcepath ] [ with WITHITEM {, WITHITEM} ]
```

WITHITEM:

```
expand = none
| expand = < ( id {, id} ) | all >
| FILTERTERM |or FILTERTERM]
```

FILTERTERM:

```
FILTERITEM [and FILTERITEM]
```

FILTERITEM:

```
( FILTERTERM |or FILTERTERM) )
| name like string
| not ( FILTERTERM |or FILTERTERM) )
| usage in ( RESOURCE_USAGE {, RESOURCE_USAGE} )
```

RESOURCE_USAGE:

```
category
| static
| synchronizing
| system
```

Description

The list named resource statement gives you a list of all the defined Named Resources. If a resource is specified, this Named Resource and, if the Named Resource is a category, all the children are listed. The list of Named Resources can be shortened accordingly by specifying a filter.
User Commands list named resource

**expand**  The *expand* option can be used to make the hierarchy visible at children level. This is done by specifying in the list the IDs of the nodes whose children are to be made visible. If *none* is specified as an expand option, only the level below the requested node is made visible.

**filter**  Named Resources can be filtered by name and/or usage by specifying filters. Refer to the official Java documentation for the syntax used for regular expressions.

**Output**

*Output*  This statement returns an output structure of type table.

**Main output description**  The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>EFFECTIVE_SUSPEND_LIMIT</td>
<td>The Suspend Limit defines the delay after which a job is submitted in a suspended state.</td>
</tr>
<tr>
<td>CALENDAR</td>
<td>This flag indicates whether calendar entries are created.</td>
</tr>
<tr>
<td>CALENDAR_HORIZON</td>
<td>The defined length of the period in days for which a calendar is created.</td>
</tr>
<tr>
<td>EFFECTIVECALENDAR_HORIZON</td>
<td>The effective length of the period in days for which a calendar is created.</td>
</tr>
</tbody>
</table>

Table 14.19.: Description of the output structure of the list scheduled event statement

User Commands

**list scope**

**Purpose**

The purpose of the list scope statement is to get a (partial) list of all defined scopes.

**Syntax**

The syntax for the list scope statement is

```
list < scope serverpath | job server serverpath > [ with EXPAND ]
```

EXPAND:

```
expand = none
| expand = < ( id [, id] ) | all >
```

**Description**

The list scope statement displays a list with the requested scope together with its children.

**expand**

The expand option can be used to make the hierarchy visible at children level. This is done by specifying in the list the IDs of the nodes whose children are to be made visible. If none is specified as an expand option, only the level below the requested node is made visible.

**Output**

This statement returns an output structure of type table.

**Main output description**

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>
</tr>
<tr>
<td>NAME</td>
<td>The object name</td>
</tr>
<tr>
<td>OWNER</td>
<td>The group owning the object</td>
</tr>
<tr>
<td>TYPE</td>
<td>The type of scope.</td>
</tr>
<tr>
<td>IS_TERMINATE</td>
<td>This flag indicates whether a termination order exists.</td>
</tr>
</tbody>
</table>

### Continuous from previous page

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HAS_ALTERED_CONFIG</td>
<td>The configuration on the server does not match the current configuration on the server.</td>
</tr>
<tr>
<td>IS_SUSPENDED</td>
<td>Indicates whether the scope is suspended.</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>The job server can only log on to the server if the Enable flag is set to Yes.</td>
</tr>
<tr>
<td>IS_REGISTERED</td>
<td>Defines whether the job server has sent a register command.</td>
</tr>
<tr>
<td>IS_CONNECTED</td>
<td>Indicates whether the job server is connected.</td>
</tr>
<tr>
<td>STATE</td>
<td>This is the current state of the resource in this scope.</td>
</tr>
<tr>
<td>PID</td>
<td>The PID is the process identification number of the job server process on the respective host system.</td>
</tr>
<tr>
<td>NODE</td>
<td>The node specifies the computer on which the job server is running.  This field has a purely documentary character.</td>
</tr>
<tr>
<td>IDLE</td>
<td>The time that has elapsed since the last command.  This only applies for job servers.</td>
</tr>
<tr>
<td>NOPDELAY</td>
<td>The time that a job server waits for “NOP”.</td>
</tr>
<tr>
<td>ERRMSG</td>
<td>This is the most recently outputted error message.</td>
</tr>
<tr>
<td>SUBSCOPES</td>
<td>The number of scopes and job servers that are present under this scope.</td>
</tr>
<tr>
<td>RESOURCES</td>
<td>The resources present in this scope are displayed here.</td>
</tr>
<tr>
<td>PRIVS</td>
<td>String containing the users privileges on the object.</td>
</tr>
</tbody>
</table>

Table 14.20.: Description of the output structure of the list scope statement
list session

Purpose

Purpose  The purpose of the list session statement is to get a list of connected sessions.

Syntax

Syntax  The syntax for the list session statement is

    list session

Description

Description  The list session statement gives you a list of the connected sessions.

Output

Output  This statement returns an output structure of type table.

Main output description  The data items of the output are described in the table below.

222 list session
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>THIS</td>
<td>The current session is indicated in this field by an asterisk (*)</td>
</tr>
<tr>
<td>SESSIONID</td>
<td>The internal server ID for the session.</td>
</tr>
<tr>
<td>PORT</td>
<td>The TCP/IP port number at which the session is connected.</td>
</tr>
<tr>
<td>START</td>
<td>Time when the connection was set up.</td>
</tr>
<tr>
<td>TYPE</td>
<td>Type of connection: user, job server or job (Jobid)</td>
</tr>
<tr>
<td>USER</td>
<td>Name of the connecting user, job server or job (Jobid)</td>
</tr>
<tr>
<td>UID</td>
<td>ID of the user, job server or job.</td>
</tr>
<tr>
<td>IP</td>
<td>IP address of the connecting sessions.</td>
</tr>
<tr>
<td>TXID</td>
<td>Number of the last transaction that was executed by the session.</td>
</tr>
<tr>
<td>IDLE</td>
<td>The number of seconds since the last statement from a session.</td>
</tr>
<tr>
<td>STATE</td>
<td>The state of the session. This is one of the following: IDLE (no activity), QUEUED (statement is waiting to be executed), ACTIVE (statement is being executed), COMMITTING (changes to a write transaction are being written), CONNECTED (not yet authenticated).</td>
</tr>
<tr>
<td>TIMEOUT</td>
<td>The idle time after which the session is automatically disconnected.</td>
</tr>
<tr>
<td>INFORMATION</td>
<td>Additional information about the session (optional).</td>
</tr>
<tr>
<td>STATEMENT</td>
<td>The statement that is currently being executed.</td>
</tr>
<tr>
<td>WAIT</td>
<td>This field is not yet documented.</td>
</tr>
</tbody>
</table>

Table 14.21.: Description of the output structure of the list session statement
**list trigger**

**Purpose**

*Purpose*  The purpose of the list trigger statement is to get a list of defined trigger.

**Syntax**

*Syntax*  The syntax for the list trigger statement is

```
list trigger

list trigger for folderpath

list trigger of folderpath

list trigger for CT_OBJECT
```

*CT_OBJECT:*

```
job definition folderpath
```

**Description**

*Description*  The list trigger statement gives you a list of all the defined triggers.

**Output**

*Output*  This statement returns an output structure of type table.

**Main output description**  The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>
</tr>
<tr>
<td>NAME</td>
<td>The object name</td>
</tr>
<tr>
<td>OBJECT_TYPE</td>
<td>The type of object in which the trigger is defined.</td>
</tr>
<tr>
<td>OBJECT_SUBTYPE</td>
<td>The subtype of the object in which the trigger is defined.</td>
</tr>
</tbody>
</table>

### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OBJECT_NAME</td>
<td>Full path name of the object in which the trigger is defined.</td>
</tr>
<tr>
<td>ACTIVE</td>
<td>The flag indicates whether the trigger is currently active.</td>
</tr>
<tr>
<td>ACTION</td>
<td>Type of triggered action: SUBMIT or RERUN.</td>
</tr>
<tr>
<td>STATES</td>
<td>A list of states that cause the trigger to be activated.</td>
</tr>
<tr>
<td>SUBMIT_TYPE</td>
<td>The object type that is submitted when the trigger is activated.</td>
</tr>
<tr>
<td>SUBMIT_NAME</td>
<td>Name of the job definition that is submitted.</td>
</tr>
<tr>
<td>SUBMIT_SE_OWNER</td>
<td>The owner of the object that is submitted.</td>
</tr>
<tr>
<td>SUBMIT_PRIVS</td>
<td>The privileges for the object that is to be submitted.</td>
</tr>
<tr>
<td>MAIN_TYPE</td>
<td>Type of main job (job/batch).</td>
</tr>
<tr>
<td>MAIN_NAME</td>
<td>Name of the main job.</td>
</tr>
<tr>
<td>MAIN_SE_OWNER</td>
<td>Owner of the main job.</td>
</tr>
<tr>
<td>MAIN_PRIVS</td>
<td>Privileges for the main job.</td>
</tr>
<tr>
<td>PARENT_TYPE</td>
<td>Type of parent job (job/batch).</td>
</tr>
<tr>
<td>PARENT_NAME</td>
<td>Name of the parent job.</td>
</tr>
<tr>
<td>PARENT_SE_OWNER</td>
<td>Owner of the parent job.</td>
</tr>
<tr>
<td>PARENT_PRIVS</td>
<td>Privileges for the parent job.</td>
</tr>
<tr>
<td>TRIGGER_TYPE</td>
<td>The trigger type that describes when it is activated.</td>
</tr>
<tr>
<td>MASTER</td>
<td>Indicates whether the trigger submitted a master or a child.</td>
</tr>
<tr>
<td>IS_INVERSE</td>
<td>Indicates whether the trigger submitted a master or a child.</td>
</tr>
<tr>
<td>SUBMIT_OWNER</td>
<td>In case of an inverse trigger, the trigger is regarded to belong to the triggered job. The trigger can be regarded as some kind of callback function. This flag has no effects on the trigger’s behaviour.</td>
</tr>
<tr>
<td>IS_CREATE</td>
<td>Indicates whether the trigger reacts to create events.</td>
</tr>
<tr>
<td>IS_CHANGE</td>
<td>Indicates whether the trigger reacts to change events.</td>
</tr>
<tr>
<td>IS_DELETE</td>
<td>Indicates whether the trigger reacts to delete events.</td>
</tr>
</tbody>
</table>

### Description of the Output Structure of the List Trigger Statement

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IS_GROUP</td>
<td>Indicates whether the trigger handles the events as a group.</td>
</tr>
<tr>
<td>MAX_RETRY</td>
<td>The maximum number of trigger activations in a single Submitted Entity.</td>
</tr>
<tr>
<td>SUSPEND</td>
<td>Specifies whether the submitted object is suspended.</td>
</tr>
<tr>
<td>RESUME_AT</td>
<td>Time of the automatic resume.</td>
</tr>
<tr>
<td>RESUME_IN</td>
<td>Number of time units until the automatic resume.</td>
</tr>
<tr>
<td>RESUME_BASE</td>
<td>Time unit for resume_in.</td>
</tr>
<tr>
<td>WARN</td>
<td>Specifies whether a warning has to be given when the activation limit is reached.</td>
</tr>
<tr>
<td>LIMIT_STATE</td>
<td>This field specifies which state the triggering job acquires if the fire limit is reached. If the triggering job has a final state already, this specification is ignored. If the value is <code>NONE</code>, no state change takes place.</td>
</tr>
<tr>
<td>CONDITION</td>
<td>Conditional expression to define the trigger condition.</td>
</tr>
<tr>
<td>CHECK_AMOUNT</td>
<td>The amount of CHECK_Base units for checking the condition in the case of non-synchronised triggers.</td>
</tr>
<tr>
<td>CHECK_BASE</td>
<td>Units for the CHECK_AMOUNT.</td>
</tr>
<tr>
<td>PRIVS</td>
<td>String containing the users privileges on the object</td>
</tr>
<tr>
<td>TAG</td>
<td>This field is not yet documented</td>
</tr>
<tr>
<td>COMMENT</td>
<td>Comment if defined</td>
</tr>
<tr>
<td>COMMENTTYPE</td>
<td>Type of comment if a comment is defined</td>
</tr>
</tbody>
</table>

Table 14.22.: Description of the output structure of the list trigger statement
list user

Purpose

The purpose of the list user statement is to get a list of all defined users.

Syntax

The syntax for the list user statement is

list user

Description

The list user statement gives you a list of all the defined users.

Output

This statement returns an output structure of type table.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>
</tr>
<tr>
<td>NAME</td>
<td>The object name</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>Flag that shows whether the user is allowed to log on.</td>
</tr>
<tr>
<td>DEFAULT_GROUP</td>
<td>The default group of the users who are being used by the owners of the object.</td>
</tr>
<tr>
<td>PRIVS</td>
<td>String containing the users privileges on the object</td>
</tr>
</tbody>
</table>

Table 14.23.: Description of the output structure of the list user statement
15. move commands
move folder

**Purpose**

*Purpose*: The purpose of the move folder statement is to rename the folder and/or to move it to some other place in the folder hierarchy.

**Syntax**

*Syntax*: The syntax for the move folder statement is

```
move folder folderpath to folderpath
```

**Description**

*Description*: The move folder command either moves the specified folder to somewhere else or renames it.

**Output**

*Output*: This statement returns a confirmation of a successful operation.
move job definition

Purpose
The purpose of the move job definition statement is to rename a scheduling entity object, and/or move it into some other folder.

Syntax
The syntax for the move job definition statement is

\[ \text{move job definition folderpath to folderpath} \]

Description
The move job definition command moves the specified job definition to the specified folder. If the destination folder does not exist, the last part of the fully qualified name is interpreted as being the new name for the job definition. The relationships to other objects are not changed.

Output
This statement returns a confirmation of a successful operation.
move named resource

Purpose

The purpose of the move named resource statement is to rename the named resource and/or to move the resource into another category.

Syntax

The syntax for the move named resource statement is

```
move named resource resourcepath to resourcepath
```

Description

The move named resource statement is used to rename a Named Resource or to reorganise categories.

If a Named Resource is moved, the specified destination has to be a category or it must not exist and its parent must be a category.

Output

This statement returns a confirmation of a successful operation
move schedule

Purpose
The purpose of the move schedule statement is to rename and/or to move the schedule to some other place in the hierarchy.

Syntax
The syntax for the move schedule statement is

\texttt{move schedule schedulepath . schedulename to schedulepath}

Description
The move schedule command either moves the specified schedule to somewhere else and/or renames it.

Output
This statement returns a confirmation of a successful operation
User Commands  move scope

**move scope**

**Purpose**

*Purpose*  The purpose of the move scope statement is to rename a scope and/or to move it to some other place within the scope hierarchy.

**Syntax**

*Syntax*  The syntax for the move scope statement is

```
move < scope serverpath | job server serverpath > to serverpath
```

**Description**

*Description*  The move scope command either moves the specified scope to somewhere else and/or renames it.

**Output**

*Output*  This statement returns a confirmation of a successful operation
16. multicommand commands
multicommand

Purpose

Purpose This statement is used to control the behaviour of the SDMS Server.

Syntax

Syntax The syntax for the multicommand statement is

\[
\text{begin multicommand commandlist end multicommand}
\]

begin multicommand commandlist end multicommand rollback

Description

Description The multicommands allow multiple SDMS commands to be executed together, i.e. in one transaction. This ensures that either all the statements are executed without any errors or nothing happens at all. Not only that, but the transaction is not interrupted by other write transactions. If the rollback keyword is specified, the transaction is undone at the end of the processing. This means that you can test whether the statements can be correctly processed (technically speaking).

Output

Output This statement returns a confirmation of a successful operation
17. register commands
register

**Purpose**

*Purpose*  The purpose of the register statement is to notify the server that the jobserver is ready to process jobs.

**Syntax**

*Syntax*  The syntax for the register statement is

```
register serverpath . servername
with pid = pid [ suspend ]
```

```
register with pid = pid
```

**Description**

*Description*  The first form is used by the operator to enable jobs to be executed by the specified job server. The second form is used by the job server itself to notify the server that it is ready to execute jobs. Jobs are scheduled for this job server (unless it is suspended) regardless of whether the server is connected or not. Refer to the deregister statement on page 144.

*pid*  The pid option provides the server with information about the job server’s process ID at operating level.

*suspend*  The suspend option causes the job server to be transferred to a suspended state.

**Output**

*Output*  This statement returns a confirmation of a successful operation.
18. rename commands
User Commands
rename environment

**rename environment**

**Purpose**

*Purpose* The purpose of the rename environment statement is to give the specified environment another name.

**Syntax**

*Syntax* The syntax for the rename environment statement is

```
rename environment environmentname to environmentname
```

**Description**

*Description* The rename environment statement is used to rename environments. Renaming an environment does not have any effect on the functionality and is only for purposes of clarity.

**Output**

*Output* This statement returns a confirmation of a successful operation.
rename event

Purpose
The purpose of the rename event is to give the specified event another name.

Syntax
The syntax for the rename event statement is

rename event eventname to eventname

Description
The rename event statement is used to give a specified event a different name.

Output
This statement returns a confirmation of a successful operation
rename exit state definition

Purpose

Purpose  The purpose of the rename exist state definition statement is to give the specified exit state definition another name.

Syntax

Syntax  The syntax for the rename exit state definition statement is

```
rename exit state definition statename to statename
```

Description

Description  The rename exit state definition statement is used to rename Exit State Definitions. Renaming an Exit State Definition does not have any effect on the functionality and is only for purposes of clarity.

Output

Output  This statement returns a confirmation of a successful operation
rename exit state mapping

Purpose
The purpose of the rename exit state mapping statement is to give the specified mapping another name.

Syntax
The syntax for the rename exit state mapping statement is

rename exit state mapping mappingname to profilename

Description
The rename exit state mapping statement is used to rename Exit State Mappings. Renaming an Exit State Mapping does not have any effect on the functionality and is only for purposes of clarity.

Output
This statement returns a confirmation of a successful operation
User Commands

rename exit state profile

rename exit state profile

Purpose

Purpose The purpose of the rename exit state profile statement is to give the specified profile another name.

Syntax

Syntax The syntax for the rename exit state profile statement is

rename exit state profile profilename to profilename

Description

Description The rename exit state profile statement is used to rename Exit State Profiles. Renaming the Exit State Profiles does not have any effect on the functionality and is only for purposes of clarity.

Output

Output This statement returns a confirmation of a successful operation
rename folder

Purpose
The purpose of the rename folder statement is to give a folder another name.

Syntax
The syntax for the rename folder statement is

```
rename folder folderpath to foldername
```

Description
The rename folder command renames the specified folder. This is done within the same parent folder. If an object with the new name already exists, this triggers an error message.

Output
This statement returns a confirmation of a successful operation
rename footprint

Purpose

Purpose

The purpose of the rename footprint statement is to give the specified footprint another name.

Syntax

Syntax

The syntax for the rename footprint statement is

rename footprint footprintname to footprintname

Description

Description

The rename footprint statement is used to give a specified footprint a different name.

Output

Output

This statement returns a confirmation of a successful operation.
rename group

Purpose
The purpose of the rename group statement is to change the name of a group without affecting any other properties.

Syntax
The syntax for the rename group statement is

rename group groupname to groupname

Description
The rename group statement is used to rename groups. Renaming a group does not have any effect on the functionality and is only for purposes of clarity.

Output
This statement returns a confirmation of a successful operation.
rename interval

Purpose
The purpose of the rename interval statement is to give a specified interval a different name.

Syntax
The syntax for the rename interval statement is:

```
rename interval
intervalname
to
intervalname
```

Description
This statement is used to give a specified interval a different name.

Output
This statement returns a confirmation of a successful operation.
rename job definition

Purpose
The purpose of the rename job definition statement is to give the job definition another name.

Syntax
The syntax for the rename job definition statement is

rename job definition folderpath to jobname

Description
The job definition rename command renames the specified job definition.

Output
This statement returns a confirmation of a successful operation.
rename named resource

Purpose

The purpose of the rename named resource statement is to give a named resource another name.

Syntax

The syntax for the rename named resource statement is

```
rename named resource resourcepath to resourcename
```

Description

The rename named resource statement is used to rename a Named Resource.

Output

This statement returns a confirmation of a successful operation.
rename resource state definition

Purpose

The purpose of the rename resource state definition statement is to rename the resource state.

Syntax

The syntax for the rename resource state definition statement is

```
rename resource state definition statename to statename
```

Description

The rename resource state definition statement is used to rename Resource State Definitions. Renaming a Resource State Definition does not have any effect on the functionality and is only for purposes of clarity.

Output

This statement returns a confirmation of a successful operation
rename resource state mapping

Purpose

The purpose of the rename resource state mapping statement is to give the specified mapping a new name.

Syntax

The syntax for the rename resource state mapping statement is

rename resource state mapping mappingname to profilename

Description

The rename resource state mapping statement is used to rename Resource State Mappings. Renaming a Resource State Mapping does not have any effect on the functionality and is only for purposes of clarity.

Output

This statement returns a confirmation of a successful operation.
rename resource state profile

Purpose

The purpose of the rename resource state profile is to give the specified resource state profile a new name.

Syntax

The syntax for the rename resource state profile statement is

rename resource state profile profilename to profilename

Description

The rename resource state profile statement is used to rename Resource State Profiles. Renaming a Resource State Profile does not have any effect on the functionality and is only for purposes of clarity.

Output

This statement returns a confirmation of a successful operation
rename schedule

Purpose

The purpose of the rename schedule statement is to give a schedule another name.

Syntax

The syntax for the rename schedule statement is

```
rename schedule schedulepath . schedulename to schedulename
```

Description

The rename schedule command renames the specified schedule.

Output

This statement returns a confirmation of a successful operation.
rename scope

Purpose
The purpose of the rename scope statement is to give a scope another name.  

Syntax
The syntax for the rename scope statement is

```
rename < scope serverpath | job server serverpath > to scopename
```

Description
The rename scope command renames the specified scope.

Output
This statement returns a confirmation of a successful operation
rename trigger

Purpose

The purpose of the rename trigger statement is to give the specified trigger another name.

Syntax

The syntax for the rename trigger statement is

```
rename trigger triggername on TRIGGEROBJECT [ < noinverse | inverse > ] to triggername
```

TRIGGEROBJECT:

- `resource resourcepath in folderpath`
- `job definition folderpath`
- `object monitor objecttypename`
- `resource resourcepath in serverpath`

Description

The rename trigger statement is used to rename the trigger. Renaming a trigger does not have any effect on the functionality and is only for purposes of clarity.

Output

This statement returns a confirmation of a successful operation
rename user

Purpose

The purpose of the rename user statement is to change the name of a user without altering any other of its properties.

Syntax

The syntax for the rename user statement is

rename user username to username

Description

The rename user statement is used to rename users. Renaming a user does not have any effect on the functionality and is only for purposes of clarity.

Output

This statement returns a confirmation of a successful operation
19. resume commands
resume

Purpose

Purpose The purpose of the resume statement is to reactivate the jobserver. See also the suspend statement on page 358.

Syntax

Syntax The syntax for the resume statement is

    resume serverpath

Description

Description The resume statement is used to reactivate a job server.

Output

Output This statement returns a confirmation of a successful operation.
20. select commands
User Commands

select

select

Purpose

The purpose of the select statement is to enable the user to issue (almost) arbitrary queries to the underlying RDBMS.

Syntax

The syntax for the select statement is

\[
\text{select-statement} \ [\text{with} \ \text{WITHITEM} \ {,} \ \text{WITHITEM}]
\]

WITHITEM:

\[
\begin{align*}
\text{identifier category} \\
\text{identifier folder} \\
\text{identifier job} \\
\text{identifier scope} \\
\text{sort (signed_integer} \ {,} \ \text{signed_integer})
\end{align*}
\]

Description

The select statement allows practically any number of database select statements to be executed by the Scheduling Server. Refer to the documentation of the database system you are using for information about the syntax that is used for the select statement.

Since executing arbitrary select statements generally represents a vulnerability, administrator privileges are required for this statement. This means that only users belonging to the admin group are allowed to use this statement.

Using the with items causes IDs to be translated into names. This function is available for all hierarchically structured object types since this operation is not always easy to perform using SQL means. It is also possible to sort the set of results after replacing the IDs. The columns that are to be used for sorting are addressed according to their position in the set of results (zero-based, i.e. the first column has the number 0).

Output

This statement returns a confirmation of a successful operation.
21. set commands
User Commands  

set parameter

Purpose

Purpose  The purpose of the set parameter statement is to set the value of the specified parameters within the context of the requesting job, respectively the specified job.

Syntax

Syntax  The syntax for the set parameter statement is

\[
\text{set parameter} \ \text{parametername} = \text{string} \ \{|, \ \text{parametername} = \text{string}\}
\]

\[
\text{set parameter} \ < \ \text{on} \ | \ \text{of} \ > \ \text{jobid} \ \text{parametername} = \text{string} \ \{|, \ \text{parametername} = \text{string}\}
\]

\[
\text{set parameter} \ < \ \text{on} \ | \ \text{of} \ > \ \text{jobid} \ \text{parametername} = \text{string} \ \{|, \ \text{parametername} = \text{string}\} \ \text{identified by} \ \text{string}
\]

Description

Description  The set parameter statements can be used to set jobs or user parameter values in the context of the job.

If the \text{identified by} option is specified, the parameter is only set if the pair \text{jobid} and \text{string} would allow a logon.

Output

Output  This statement returns a confirmation of a successful operation
22. show commands
show comment

Purpose

The purpose of the show comment statement is to show the comment for the specified object.

Syntax

The syntax for the show comment statement is

```
show comment on OBJECTURL
```

OBJECTURL:

- `distribution distributionname for pool` resourcepath in serverpath
- `environment` environmentname
- `exit state definition` statename
- `exit state mapping` mappingname
- `exit state profile` profilename
- `event` eventname
- `resource` resourcepath in folderpath
- `folder` folderpath
- `footprint` footprintname
- `group` groupname
- `interval` intervalname
- `job definition` folderpath
- `job` jobid
- `named resource` resourcepath
- `parameter` parametername of PARAM_LOC
- `resource state definition` statename
- `resource state mapping` mappingname
- `resource state profile` profilename
- `scheduled event` schedulepath . eventname
- `schedule` schedulepath
- resource resourcepath in serverpath
- `< scope serverpath | job server serverpath >`
- `trigger` triggername on TRIGGEROBJECT [ <noinverse | inverse > ]
- `user` username

PARAM_LOC:

- `folder` folderpath
- `job definition` folderpath
The show comment statement is used to display the saved comment for the specified object. If no comment on the object exists, this is not regarded as being an error; instead, an empty output structure is created and returned. This empty output structure naturally corresponds to the output structure described below, so that it can be easily evaluated by programs without any exception handling.

Output

This statement returns an output structure of type table.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>System-wide unique object number.</td>
</tr>
<tr>
<td>TAG</td>
<td>The comment tag is a headline of the comment block. It is an optional field.</td>
</tr>
<tr>
<td>COMMENT</td>
<td>The comment on the specified object.</td>
</tr>
<tr>
<td>COMMENTTYPE</td>
<td>Type of comment, text or URL.</td>
</tr>
<tr>
<td>CREATOR</td>
<td>Name of the user who created this pool.</td>
</tr>
<tr>
<td>CREATE_TIME</td>
<td>The creation time.</td>
</tr>
<tr>
<td>CHANGER</td>
<td>Name of the last user who modified this pool.</td>
</tr>
<tr>
<td>CHANGE_TIME</td>
<td>Time of the last modification.</td>
</tr>
<tr>
<td>PRIVS</td>
<td>Abbreviation for the privileges for this object held by the requesting user.</td>
</tr>
</tbody>
</table>

Table 22.1.: Description of the output structure of the show comment statement
show environment

Purpose

The purpose of the show environment statement is to get detailed information about the specified environment.

Syntax

The syntax for the show environment statement is

```
show environment environmentname [ with EXPAND ]
```

<table>
<thead>
<tr>
<th>EXPAND:</th>
</tr>
</thead>
<tbody>
<tr>
<td>expand = none</td>
</tr>
<tr>
<td>expand = &lt; id [, id] &gt;</td>
</tr>
<tr>
<td>all</td>
</tr>
</tbody>
</table>

Description

The show environment statement gives you detailed information about the specified environment.

expand Since the number of job definitions in the table JOB_DEFINITIONS can become very large, by default they are not all displayed. If the option expand = all is used, all the job definitions as well as their parent folder and the folder hierarchy are outputted. Individual paths in the hierarchy can be selected by specifying individual (folder) IDs.

Output

This statement returns an output structure of type record.

Main output description The data items of the output are described in the table below.

<table>
<thead>

show event

Purpose

The purpose of the show event statement is to get detailed information about the specified event.

Syntax

The syntax for the show event statement is

`show event eventname`

Description

The show event statement gives you detailed information about the specified event.

Output

This statement returns an output structure of type record.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>
</tr>
<tr>
<td>NAME</td>
<td>Name of the show event</td>
</tr>
<tr>
<td>OWNER</td>
<td>The group owning the object</td>
</tr>
<tr>
<td>SCHEDULING_ENTITY</td>
<td>Batch or job that is submitted when this event occurs.</td>
</tr>
<tr>
<td>CREATOR</td>
<td>Name of the user created the object</td>
</tr>
<tr>
<td>CREATE_TIME</td>
<td>Date and time of object creation</td>
</tr>

show exit state definition

**Purpose**

The purpose of the show exit state definition statement is to get detailed information about the specified exit state definition.

**Syntax**

The syntax for the show exit state definition statement is

```
show exit state definition statename
```

**Description**

The show exit state definition statement gives you detailed information about the specified Exit State Definition.

**Output**

This statement returns an output structure of type record.

**Main output description**

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>

Table 22.7.: Description of the output structure of the show exit state definition statement
show exit state mapping

Purpose

The purpose of the show exist state mapping statement is to get detailed information about the specified mapping.

Syntax

The syntax for the show exit state mapping statement is

```
show exit state mapping mappingname
```

Description

The show exit state mapping statement gives you detailed information about the specified mapping.

Output

This statement returns an output structure of type record.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>

Table 22.14.: Description of the output structure of the show folder subtable
**User Commands**

**show footprint**

**show footprint**

**Purpose**

The purpose of the `show footprint` statement is to get detailed information about the specified footprint.

**Syntax**

The syntax for the `show footprint` statement is

```plaintext
show footprint footprintname [ with EXPAND ]
```

**Description**

The `show footprint` statement gives you detailed information about the specified footprint.

**expand** Since the number of job definitions in the table JOB_DEFINITIONS can become very large, by default they are not all displayed. If the option `expand = all` is used, all the job definitions as well as their parent folder and the folder hierarchy are outputted. Individual paths in the hierarchy can be selected by specifying individual (folder) IDs.

**Output**

This statement returns an output structure of type record.

**Main output description** The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>

show interval

Purpose

The purpose of the show interval statement is to get detailed information about the interval.

Syntax

The syntax for the show interval statement is

```
show interval intervalname
[ with expand [ < = datetime | = datetime - datetime > ] ]
```

Description

The show interval statement displays detailed information about a interval. No rising edges are displayed in the absence of an expand clause. The expand clause can be used to specify a period for which the edges are to be shown.

Output

This statement returns an output structure of type record.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>

User Commands

Field | Description
--- | ---
FILTER | Name(s) of the intervals that filter (multiplication) the output of this interval more finely.
CREATOR | Name of the user created the object
CREATE_TIME | Date and time of object creation
CHANGER | Name of the last user changed the object
CHANGE_TIME | Date and time of object change
PRIVS | String containing the users privileges on the object
COMMENT | Comment if defined
COMMENTTYPE | Type of comment if a comment is defined

Table 22.21.: Description of the output structure of the show interval statement

**SELECTION** The layout of the SELECTION table is shown in the table below.

Field | Description
--- | ---
ID | The repository object id
VALUE | Number of the selected edge.
PERIOD_FROM | Beginning of the period in which all the occurring edges are considered to have been selected.
PERIOD_TO | End of the period in which all the occurring edges are considered to have been selected.

Table 22.22.: Description of the output structure of the show interval subtable

**FILTER** The layout of the FILTER table is shown in the table below.

Field | Description
--- | ---
ID | The repository object id
CHILD | Name of the filtering interval.

Table 22.23.: Description of the output structure of the show interval subtable
show job

Purpose

The purpose of the show job statement is to get detailed information about the specified job.

Syntax

The syntax for the show job statement is

```
show job [WITHITEM {, WITHITEM}]
```

```
show job submittag = string [WITHITEM {, WITHITEM}]
```

WITHITEM:

```
filter = (FILTERITEM {, FILTERITEM})
```

recursive audit

FILTERITEM:

```
cancel
change priority
clear warning
comment
ignore named resource
ignore resource
ignore dependency [recursive]
job in error
kill
renice
rerun [recursive]
restartable
resume
set exit state
set resource state
set state
set warning
submit [suspend]
suspend
timeout
trigger failure
trigger submit
unreachable
```
User Commands  

show job

Description

The show job statement gives you detailed information about the specified job. The job can be specified using either its ID or, if a submit tag was specified during the submit, the submit tag.

The filter option is used for selecting audit entries. If the filter option is not specified, all the audit entries are shown. Otherwise, only entries of the type specified in the filter are outputted.

The recursive audit option collects all the audit messages for the displayed job and its direct or indirect children.

Output

This statement returns an output structure of type record.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>
</tr>
<tr>
<td>SE_NAME</td>
<td>The full path name of the object.</td>
</tr>
<tr>
<td>SE_OWNER</td>
<td>Owner of the object.</td>
</tr>
<tr>
<td>SE_TYPE</td>
<td>The se_type is the object type (JOB, BATCH or MILESTONE).</td>
</tr>
<tr>
<td>SE_RUN_PROGRAM</td>
<td>The Run Program line in the job definition.</td>
</tr>
<tr>
<td>SE_RERUN_PROGRAM</td>
<td>The Rerun Program line in the job definition.</td>
</tr>
<tr>
<td>SE_KILL_PROGRAM</td>
<td>The Kill Program line in the job definition.</td>
</tr>
<tr>
<td>SE_WORKDIR</td>
<td>The Workdir of the job definition.</td>
</tr>
<tr>
<td>SE_LOGFILE</td>
<td>The log file of the job definition.</td>
</tr>
<tr>
<td>SE_TRUNC_LOG</td>
<td>Defines whether the log file is to be truncated before the process starts or if the log information is to be appended.</td>
</tr>
<tr>
<td>SE_ERRLOGFILE</td>
<td>The error log file of the job definition.</td>
</tr>
<tr>
<td>SE_TRUNC_ERRLOG</td>
<td>Defines whether the log file is to be truncated before the process starts or if the log information is to be appended.</td>
</tr>
<tr>
<td>SE_EXPECTED_RUNTIME</td>
<td>The anticipated runtime of the job definition.</td>
</tr>
<tr>
<td>SE_PRIORITY</td>
<td>Priority/nice value of the job definition.</td>
</tr>
<tr>
<td>SE_SUBMIT_SUSPENDED</td>
<td>The Suspend Flag of the object.</td>
</tr>
<tr>
<td>SE_MASTER_SUBMITTABLE</td>
<td>The Master Submittable Flag of the object.</td>
</tr>
</tbody>
</table>

### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SE_DEPENDENCY_MODE</td>
<td>The Dependency Mode of the object.</td>
</tr>
<tr>
<td>SE_ESP_NAME</td>
<td>The Exit State Profile of the object.</td>
</tr>
<tr>
<td>SE_ESM_NAME</td>
<td>The Exit State Mapping the job definition.</td>
</tr>
<tr>
<td>SE_ENV_NAME</td>
<td>The environment of the job definition.</td>
</tr>
<tr>
<td>SE_FP_NAME</td>
<td>The footprint of the job definition.</td>
</tr>
<tr>
<td>MASTER_ID</td>
<td>The object ID of the object at the top level in the hierarchy of this object.</td>
</tr>
<tr>
<td>CHILD_TAG</td>
<td>Tag for exclusive identifying jobs that have been submitted several times as children of the same job.</td>
</tr>
<tr>
<td>SE_VERSION</td>
<td>The version of definitions that are valid for this Submitted Entity.</td>
</tr>
<tr>
<td>OWNER</td>
<td>The group owning the object</td>
</tr>
<tr>
<td>PARENT_ID</td>
<td>The parent object in the submission hierarchy.</td>
</tr>
<tr>
<td>SCOPE_ID</td>
<td>The ID of the scope.</td>
</tr>
<tr>
<td>HTTPHOST</td>
<td>The host name of the scope for accessing log files via HTTP.</td>
</tr>
<tr>
<td>HTTPPORT</td>
<td>The HTTP port number of the job server for accessing log files via HTTP.</td>
</tr>
<tr>
<td>IS_STATIC</td>
<td>Flag indicating the static or dynamic submits of this job.</td>
</tr>
<tr>
<td>MERGE_MODE</td>
<td>Indicates how multiple submits of the same defined object are handled in the current Master Run.</td>
</tr>
<tr>
<td>STATE</td>
<td>The state of the job (not to be confused with the Exit State).</td>
</tr>
<tr>
<td>IS_DISABLED</td>
<td>Indicates whether the submitted entity was submitted disabled.</td>
</tr>
<tr>
<td>IS_CANCELLED</td>
<td>Shows a Cancel operation that was performed on the job.</td>
</tr>
<tr>
<td>JOB_ESD_ID</td>
<td>The Exit State of the job after it has been executed.</td>
</tr>
<tr>
<td>JOB_ESD_PREF</td>
<td>The preference for merging the Job Exit States with the Child States.</td>
</tr>
<tr>
<td>JOB_IS_FINAL</td>
<td>Flag indicating the final state of the job.</td>
</tr>
<tr>
<td>JOB_IS_RESTARTABLE</td>
<td>A flag indicating that this job is restartable.</td>
</tr>
<tr>
<td>FINAL_ESD_ID</td>
<td>The final (merged) Exit State of the object.</td>
</tr>
</tbody>
</table>

## Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXIT_CODE</td>
<td>The Exit Code of the last command execution.</td>
</tr>
<tr>
<td>COMMANDLINE</td>
<td>The created command line that is used for the first execution.</td>
</tr>
<tr>
<td>RR_COMMANDLINE</td>
<td>Created rerun command line that is used for the last executed rerun.</td>
</tr>
<tr>
<td>WORKDIR</td>
<td>The created Workdir.</td>
</tr>
<tr>
<td>LOGFILE</td>
<td>The created log file.</td>
</tr>
<tr>
<td>ERRLOGFILE</td>
<td>The created error log file.</td>
</tr>
<tr>
<td>PID</td>
<td>The process ID of the controller process.</td>
</tr>
<tr>
<td>EXT_PID</td>
<td>The process ID of the user process.</td>
</tr>
</tbody>
</table>
| ERROR_MSG           | If an error occurred while the job was being executed in the Time Schedul-
                     | ing, the returned error message is displayed in the Error Message field.   |
|                     | If no error occurred, this field remains empty.                            |
| KILL_ID             | The Submitted Entity ID of the submitted Kill Job.                         |
| KILL_EXIT_CODE      | The Exit Code of the last executed Kill Program.                           |
| IS_SUSPENDED        | Flag indicating whether the object is suspended.                           |
| IS_SUSPENDED_LOCAL  | Flag indicating whether the object is locally suspended (for restart trig-
                     | ger with suspend).                                                        |
| PRIORITY            | The current priority of the job.                                           |
| RAW_PRIORITY        | The raw priority value of the job. Unlike the priority, this value is prac-
                     | tically unbounded.                                                        |
|                     | This is required in order to be able to restore the correct priority after
                     | Nice Profile manipulations.                                                |
| NICEVALUE           | The current nice value of the job.                                         |
| NP_NICEVALUE        | The $np\_nicevalue$ is the nice value which is the effect of activating (an-
                     | d deactivating) nice profiles.                                            |
| MIN_PRIORITY        | Minimum effective priority that can be achieved through natural aging.     |
| AGING_AMOUNT        | The number of time units after which the effective priority is incremented
                     | by 1.                                                                      |
| AGING_BASE          | The time unit that is used for the aging interval.                         |
| DYNAMIC_PRIORITY    | The calculated priority that is currently being used by the system.       |
| PARENT_SUSPENDED    | The number of parents that have been suspended.                            |

### Field| Description
---|---
**REQUIRED_PRIVS** | The privileges for the required object.
**STATE** | The state of the dependency (OPEN, FILLED or FAILED).
**DD_ID** | ID of the Dependency Definition object.
**DD_NAME** | Name of the Dependency Definition (deprecated).
**DD_DEPENDENT_NAME** | The full path name of the object.
**DD_DEPENDENT_TYPE** | The type of dependent object.
**DD_DEPENDENT_PRIVS** | Privileges for the dependent object.
**DD_REQUIRED_NAME** | Path name of the definition of the dependent object.
**DD_REQUIRED_TYPE** | The type of required object.
**DD_REQUIRED_PRIVS** | The privileges for the required object definition.
**DD_UNRESOLVED_HANDLING** | Specifies how to handle unresolvable dependencies during a submit.
**DD_MODE** | Defines whether just the required job itself or the required job together with its children have to be final.
**DD_STATES** | List of Exit States that the required object have to achieve to fulfill the dependency.
**JOB_STATE** | In the Job State list, you can filter for jobs that have the entered Job State.
**IS_SUSPENDED** | Flag indicating whether the object is suspended.
**PARENT_SUSPENDED** | Job is suspended because its parent is suspended.
**CNT_SUBMITTED** | The number of children in a Submitted state.
**CNT_DEPENDENCY_WAIT** | The number of children in a Dependency_Wait state.
**CNT_SYNCHRONIZE_WAIT** | The number of children in a Synchronize_Wait state.
**CNT_RESOURCE_WAIT** | The number of children in a Resource_Wait state.
**CNT_RUNNABLE** | The number of children in a Runnable state.
**CNT_STARTING** | The number of children in a Starting state.
**CNT_STARTED** | The number of children in a Started state.
**CNT_RUNNING** | The number of children in a Running state.
**CNT_TO_KILL** | The number of children in a To_Kill state.

**show job definition**

**Purpose**

The purpose of the show job definition statement is to get detailed information about the specified job definition.

**Syntax**

The syntax for the show job definition statement is

```
show job definition folderpath
```

**Description**

The show job definition statement gives you detailed information about the specified job definition.

**Output**

This statement returns an output structure of type record.

**Main output description**

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>
</tr>
<tr>
<td>NAME</td>
<td>The full path name of the job definition.</td>
</tr>
<tr>
<td>OWNER</td>
<td>The group owning the object</td>
</tr>
<tr>
<td>TYPE</td>
<td>The object type (Batch, Job or Milestone).</td>
</tr>
<tr>
<td>INHERIT_PRIVS</td>
<td>Privileges that are inherited from the parent folder.</td>
</tr>
<tr>
<td>RUN_PROGRAM</td>
<td>The command line for executing a job for the first time.</td>
</tr>
<tr>
<td>RERUN_PROGRAM</td>
<td>The command line for restarting a submitted job.</td>
</tr>
<tr>
<td>KILL_PROGRAM</td>
<td>The command line for executing the deletion of a running job.</td>
</tr>
<tr>
<td>WORKDIR</td>
<td>The working directory from where the command is to be executed.</td>
</tr>
</tbody>
</table>

**REQUIRED_JOBS**  The layout of the REQUIRED_JOBS table is shown in the table below.
show job definition | User Commands

Field | Description
--- | ---
**ID** | The repository object id
**NAME** | The object name
**DEPENDENTNAME** | The full path name of the dependent object.
**DEPENDENTTYPE** | The type of dependent object (JOB, BATCH or MILESTONE).
**DEPENDENTPRIVS** | String containing the user privileges of the dependent object.
**REQUIREDNAME** | The full path name of the required object.
**REQUIREDTYPE** | The type of required object (JOB, BATCH or MILESTONE).
**REQUIREDPRIVS** | String containing the user privileges of the required object.
**UNRESOLVED_HANDLING** | Defines what to do if the required object cannot be found.
**MODE** | Defines whether dependencies are to be handled as being fulfilled in the case of jobs in a final state (JOB_FINAL) or final states of objects contain the child objects (ALL_FINAL).
**STATE_SELECTION** | The State Selection defines how the required Exit States are determined. The options here are FINAL, ALL_REACHABLE, UNREACHABLE and DEFAULT. In the case of FINAL, the required Exit States can be explicitly listed.
**CONDITION** | The additional conditions must be fulfilled.
**STATES** | Comma-separated list of permitted Exit States that the required object has to achieve to fulfil the dependencies. If an additional condition has been specified, it is shown after the colon.

<td>The origin of the resource request (REQUIREMENT, FOOTPRINT, FOLDER or ENVIRONMENT).</td>
</tr>
<tr>
<td>ORIGIN</td>
<td>Name of the Resource Request Definition, invalid in the case of a complete request.</td>
</tr>
<tr>
<td>CONDITION</td>
<td>The optional condition that can be defined for requests for Static Resources.</td>
</tr>
</tbody>
</table>

Table 22.39.: Description of the output structure of the show job definition subtable
show named resource

Purpose

The purpose of the show named resource statement is to get detailed information about the named resource.

Syntax

The syntax for the show named resource statement is

```
show named resource resourcepath [with EXPAND]
```

EXPAND:

```text
expand = none
| expand = < ( id [, id] ) | all >
```

Description

The show named resource statement gives you detailed information about the Named Resource.

**expand** Since the number of job definitions in the table JOB_DEFINITIONS can become very large, by default they are not all displayed. If the option `expand = all` is used, all the job definitions as well as their parent folder and the folder hierarchy are outputted. Individual paths in the hierarchy can be selected by specifying individual (folder) IDs.

Output

This statement returns an output structure of type record.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>

Table 22.43.: Description of the output structure of the show named resource subtable
show resource

Purpose

The purpose of the show resource statement is to get detailed information about the resource.

Syntax

The syntax for the show resource statement is

```
show RESOURCE_URL
```

```
RESOURCE_URL:

resource resourcepath in folderpath
| resource resourcepath in serverpath
```

Description

The show resource statement gives you detailed information about the resource.

Output

This statement returns an output structure of type record.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>

</table>

Table 22.46.: Description of the output structure of the show resource subtable
show resource state definition

Purpose

The purpose of the show resource state definition is to get detailed information about the specified resource state definition.

Syntax

The syntax for the show resource state definition statement is

show resource state definition statename

Description

The show resource state definition statement gives you detailed information about the Resource State Definition.

Output

This statement returns an output structure of type record.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

Table 22.47.: Description of the output structure of the show resource state definition statement
show resource state mapping

Purpose

Purpose The purpose of the show resource state mapping statement is to get detailed information about the specified mapping.

Syntax

Syntax The syntax for the show resource state mapping statement is

```
show resource state mapping profilename
```

Description

Description The show resource state mapping statement gives you detailed information about the specified mapping.

Output

Output This statement returns an output structure of type record.

Main output description The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>

Table 22.53.: Description of the output structure of the show scheduled event statement
show scope

Purpose

The purpose of the show scope statement is to get detailed information about a scope.

Syntax

The syntax for the show scope statement is

```
show < scope serverpath | job server serverpath > [ with expand ]
```

**EXPAND:**

```
expand = none
| expand = < ( id [, id] ) | all >
```

Description

The show scope statement gives you detailed information about the scope.

Output

This statement returns an output structure of type record.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>The repository object id</td>

show session

Purpose

The purpose of the show session statement is to get more detailed information about the specified or the current session.

Syntax

The syntax for the show session statement is

```
show session [ sid ]
```

Description

The show session statement gives you detailed information about the specified or current session.

Output

This statement returns an output structure of type record.

Main output description

The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>THIS</td>
<td>With This, the proprietary session is shown with an asterisk.</td>

23. shutdown commands
**shutdown**

**Purpose**

*Purpose* The purpose of the shutdown statement is to instruct the addressed job servers to terminate.

**Syntax**

*Syntax* The syntax for the shutdown statement is

```plaintext
shutdown serverpath
```

**Description**

*Description* The shutdown statement is used to shut down the addressed job server.

**Output**

*Output* This statement returns a confirmation of a successful operation.
24. stop commands
User Commands stop server

stop server

Purpose

Purpose The purpose of the stop server statement is to instruct the server to terminate.

Syntax

Syntax The syntax for the stop server statement is

stop server

stop server kill

Description

Description The stop server statement is used to shut down the server. If this should not function correctly for any reason, the server can also be forced to shut down using kill.

Output

Output This statement returns a confirmation of a successful operation
25. submit commands
User Commands submit

**submit**

**Purpose**

*Purpose* The purpose of the submit statement is to execute a master batch or job as well as all defined children.

**Syntax**

*Syntax* The syntax for the submit statement is

```
submit folderpath [ with WITHITEM {, WITHITEM} ]
```

```
submit aliasname [ with WITHITEM {, WITHITEM} ]
```

WITHITEM:

- check only
- childtag = string
- nicevalue = signed_integer
- parameter = none
- parameter = ( PARAM {, PARAM} )
- < noresume | resume in period | resume at datetime >
- submittag = string
- < nosuspend | suspend >
- unresolved = < error | ignore | suspend | defer >
- group = groupname

**Description**

*Description* The submit statement is used to submit a job or batch. There are two kinds of submit command:

- The first kind is used by users, who can also be programs, and the Time Scheduling Module. This form submits Master Jobs and Batches.
- The second form of the statement is used by jobs to submit dynamic children.
check only  The check only option is used to verify whether a Master Submittable Batch or Job can be submitted. This means that a check is run to ascertain whether all the dependencies can be fulfilled and all the referenced parameters are defined. Whether the jobs can be executed in any scope or not is not verified. This is a situation that can arise at any point during the runtime. Positive feedback means that, from the system’s perspective, the job or batch can be submitted.

childtag  The childtag option is used by jobs to submit several instances of the same Scheduling Entity and to be able to differentiate between them. An error is triggered if the same Scheduling Entity is submitted twice using the same childtag. The content of the childtag has no further significance for the Scheduling System. The maximum length for a childtag is 70 characters. The childtag option is ignored in the case of a Master Submit.

group  The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

nicevalue  The nicevalue option defines a correction that is used for the calculation of the priorities for the job and its children. Values between -100 and 100 are permitted.

parameter  The parameter option is used to specify the value of Job Parameters for the submit. The parameters are set in the scope of the Master Batch or Job. This means that if parameters are specified that are not defined in the Master Batch or Job, these parameters are invisible to any children.

submittag  If the submittag is specified, it must have a unique name for the Submitted Entity. This tag was introduced to be able to programmatically submit jobs and batches and to resubmit the job or batch with the same tag following a crash of one of the components. If the job submit was successful the first time, the second submit will report an error. If not, the second submit will succeed.

unresolved  The unresolved option defines how the server is to react to unresolved dependencies. This option is mainly used if parts of a batch are submitted following repair work. The faulty part is normally cancelled and then resubmitted as a Master Run. In this case the previous dependencies have to be ignored otherwise the submit will fail.
**User Commands**

**submit**

**suspend** The suspend option is used to submit jobs or batches and to suspend them at the same time. If nothing is defined, they are not suspended. This can be explicitly specified at the submit time. If a job or batch was suspended, neither it nor its children are started. If a job is already running, it will not reach a Final State if it is suspended.

**resume** The resume option can be used together with the suspend option to cause a delayed execution. There are two ways to do this. A delay can be achieved by specifying either the number of time units for the delay the time when the job or batch is to be activated. This option can be used to reproduce the `at` functionality without creating a schedule.

**Output**

**Output** This statement returns an output structure of type record.

**Main output description** The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>ID of the Submitted Entity.</td>
</tr>
</tbody>
</table>

Table 25.1: Description of the output structure of the submit statement
26. suspend commands
suspend

Purpose

Purpose The purpose of the suspend statement is to prevent further jobs to be executed by this jobserver. See also the resume statement on page 260.

Syntax

Syntax The syntax for the suspend statement is

    suspend serverpath

Description

Description The suspend statement prevents further jobs from being executed by this job server.

Output

Output This statement returns a confirmation of a successful operation
Part III.

Jobserver Commands
27. Jobserver Commands
alter job

Purpose

The purpose of the alter job statement is to change properties of the specified job. This statement is used by job administrators, job servers, and by the job itself.

Syntax

The syntax for the alter job statement is

```
alter job jobid
with WITHITEM {, WITHITEM}

alter job
with WITHITEM {, WITHITEM}
```

WITHITEM:

```
< suspend | suspend restrict | suspend local | suspend local restrict >
cancel
clear warning
comment = string
error text = string
exec pid = pid
exit code = signed_integer
exit state = statename [ force ]
ext pid = pid
ignore resource = ( id [, id] )
ignore dependency = ( jobid [ recursive ] {, jobid [ recursive ]} )
kill
nicevalue = signed_integer
priority = integer
renice = signed_integer
rerun [ recursive ]
resume
< noresume | resume in period | resume at datetime >
run = integer
state = JOBSTATE
timestamp = string
warning = string
```

JOBSTATE:
alter job

### Description

The alter job command is used for several purposes. Firstly, job servers use this command to document the progress of a job. All the state transitions a job undergoes during the time when the job is the responsibility of a job server are performed using the alter job command.

Secondly, some changes such as ignoring dependencies or resources, as well as changing the priority of a job, are carried out manually by an administrator. The Exit State of a job in a Pending State can be set by the job itself or by a process that knows the job ID and key of the job that is to be changed.

### cancel

The cancel option is used to cancel the addressed job and all non-Final Children. A job can only be cancelled if neither the job itself nor one of its children is active. Cancelling a running job will set the job in a cancelling state. The effective cancel is postponed until the job is finished.

If a Scheduling Entity is dependent upon the cancelled job, it can become unreachable. In this case the dependent job does not acquire the Unreachable Exit State defined in the Exit State Profiles, but is set as having the Job State “Unreachable”. It is the operator’s task to restore this job back to the job state “Dependency Wait” by ignoring dependencies or even to cancel it.

Cancelled jobs are considered to be just like Final Jobs without a Final Exit. This means that the parents of a cancelled job become final without taking into consideration the Exit State of the cancelled job. In this case the dependent jobs of the parents continue running normally.

The cancel option can only be used by users.

### comment

The comment option is used to document an action or to add a comment to the job. Comments can have a maximum length of 1024 characters. Any number of comments can be saved for a job.

Some comments are saved automatically. For example, if a job attains a Restartable State, a log is written to document this fact.
Jobserver Commands

**error text**  The error text option is used to write error information about a job. This can be done by the responsible job server or a user. The server can write this text itself as well. This option is normally used if the job server cannot start the corresponding process. Possible cases are where it is not possible to switch to the defined working directory, if the executable program cannot be found, or when opening the error log file triggers an error.

**exec pid**  The exec pid option is used exclusively by the job server to set the process ID of the control process within the server.

**exit code**  The exit code option is used by the job server to tell the repository server with which Exit Code the process has finished. The repository server now calculates the matching Exit State from the Exit State Mapping that was used.

**exit state**  The exit state option is used by jobs in a pending state to set their state to another value. This is usually a Restartable or Final State. Alternatively, this option can be used by administrators to set the state of a non-final job. If the Force Flag is not being used, the only states that can be set are those which are theoretically attainable by applying the Exit State Mapping to any Exit Code. The set state must exist in the Exit State Profile.

**ext pid**  The ext pid option is used exclusively by the job server to set the process ID of the started user process.

**ignore resource**  The ignore resource option is used to revoke individual Resource Requests. The ignored resource is then no longer requested. If the parameters of a resource are being referenced, that resource cannot be ignored. If invalid IDs have been specified, it is skipped. All other specified resources are ignored. Invalid IDs in this context are the IDs of resources that are not requested by the job. The ignoring of resources is logged.

**ignore dependency**  The ignore dependency option is used to ignore defined dependencies. If the recursive flag is used, not only do the job or batch ignore the dependencies, but its children do so as well.

**kill**  The kill option is used to submit the defined Kill Job. If no Kill Job has been defined, it is not possible to forcibly terminate the job from within BICSuite. The job obviously has to be active, that means it must be running, killed or broken_active.
The last two states are not regular cases. When a Kill Job has been submitted, the Job State is **to_kill**. After the Kill Job has terminated, the Job State of the killed job is set to **killed** unless it has been completed, in which case it is **finished** or **final**. This means that the job with the Job State **killed** is always still running and that at least one attempt has been made to terminate it.

**nicevalue**  The nicevalue option is used to change the priority or the nicevalue of a job or batch and all of its children. If a child has several parents, any changes you make can, but do not necessarily have to, affect the priority of the child in the nicevalue of one of the parents. Where there are several parents, the maximum nicevalue is searched for.

This means that if Job C has three Parents P1, P2 and P3, whereby P1 sets a nice value of 0, P2 sets a nicevalue of 10 and P3 a nicevalue of -10, the effective nicevalue is -10. (The lower the nicevalue the better). If the nicevalue for P2 is changed to -5, nothing happens because the -10 of P3 is better than -5. If the nicevalue of P3 falls to 0, the new effective nicevalue for Job C is -5.

The nicevalues can have values between -100 and 100. Values that exceed this range are tacitly adjusted.

**priority**  The priority option is used to change the (static) priority of a job. Because batches and milestones are not executed, priorities are irrelevant to them.

Changing the priority only affects the changed job. Valid values lie between 0 and 100. In this case, 100 corresponds to the lowest priority and 0 is the highest priority.

When calculating the dynamic priority of a job, the scheduler begins with the static priority and adjusts it according to how long the job has already been waiting. If more than one job has the same dynamic priority, the job with the lowest job ID is scheduled first.

**renice**  The renice option is similar to the nicevalue option with the difference that the renice option functions relatively while the nicevalue option functions absolutely. If some batches have a nicevalue of 10, a renice of -5 causes the nicevalue to rise to 5. (It rises because the lower the number, the higher the priority).

**rerun**  The rerun option is used to restart a job in a Restartable State. If you attempt to restart a job that is not restartable, an error message is displayed. A job is restartable if it is in a Restartable State or it has the Job State **error** or **broken_finished**.

If the **recursive** flag has been specified, the job itself and all its direct and indirect children that are in a Restartable State are restarted. If the job itself is final, this is not considered to be an error. It is therefore possible to recursively restart batches.
resume  The resume option is used to reactivate a suspended job or batch. There are two ways to do this. The suspended job or batch can either be reactivated immediately or a delay can be set. A delay can be achieved by specifying either the number of time units for the delay or the time when the job or batch is to be activated. For details about specifying a time, refer to the overview on page 6. The resume option can be used together with the suspend option. Here, the job is suspended and then resumed again after (or at) a specified time.

run  The run option is used by the job server to ensure that the modified job matches the current version. Theoretically, the computer could crash after a job has been started by a job server. To complete the work, the job is manually restarted from another job server. After the first system has been booted, the job server can attempt to change the job state to broken_finished without knowing anything about what happened after the crash. Using the run option then prevents the wrong state from being set.

state  The state option is mainly used by job servers, but it can also be used by administrators. It is not recommended to do so unless you know exactly what you are doing. The usual procedure is that the job server sets the state of a job from starting to started, from started to running, and from running to finished. In the event of a crash or any other problems, it is possible for the job server to set the job state to broken_active or broken_finished. This means that the Exit Code of the process is not available and the Exit State has to be set manually.

suspend  The suspend option is used to suspend a batch or job. It always functions recursively. If a parent is suspended, its children are all suspended as well. The resume option is used to reverse the situation. The effect of the restrict option is that cwa resume can be done by members of the group ADMIN only.

timestamp  The timestamp option is used by the job server to set the timestamps of the state transition in keeping with the local time from the perspective of job server.

Output

Output  This statement returns a confirmation of a successful operation.
alter jobserver

Purpose

The purpose of the alter jobserver statement is to alter properties of a jobserver.

Syntax

The syntax for the alter jobserver statement is

```
alter [existing] job server
with < fatal | nonfatal > error text = string
```

```
alter [existing] job server
with dynamic PARAMETERS
```

PARAMETERS:

```
parameter = none
| parameter = ( PARAMETERSPEC {, PARAMETERSPEC} )
```

PARAMETERSPEC:

```
parametername = < string | number >
```

Description

The alter scope command is both a user command and a job server command. It is used as a user command to change the configuration or other properties of a scope or job server. Further details are described in the create scope command on page 129.

The syntax of the user command corresponds to the first form of the alter scope command. As a job server command, it is used to notify the server about any errors. If the Fatal Flag is used, this means that the job server is shutting down. In the other case, the job server continues running.

The third form of the alter jobserver command is also used by the job server. The job server publishes the values of its dynamic parameter. The server uses published values to resolve parameters in the command line and log file information when retrieving a job.

Output

This statement returns a confirmation of a successful operation.
connect

Purpose

The purpose of the connect statement is to authenticate a jobserver to the server.

Syntax

The syntax for the connect statement is

```
connect job server serverpath . servername identified by string [ with WITHITEM {, WITHITEM} ]
```

WITHITEM:

- `command` = ( sdms-command )
- `protocol` = PROTOCOL
- `session` = string
- `timeout` = integer
- `< trace | notrace >`
- `trace level` = integer

PROTOCOL:

- json
- line
- perl
- python
- serial
- xml

Description

The connect command is used to authenticate the connected process on the server to. A communication protocol can be optionally specified. The default protocol is line.

The selected protocol defines the output format. All protocols except for serial return ASCII output. The protocol serial returns a serialized Java object.

An executable command can also be returned when the connection is established. In this case, the output of the accompanying command is used as the output for the connect command. If the command fails, but the connect was successful, the connection remains active.

An example for all protocols except the serial protocol is given below.
**The line protocol**  The line protocol only returns an ASCII text as the result from a command.

connect donald identified by 'duck' with protocol = line;

Connect

CONNECT_TIME : 19 Jan 2005 11:12:43 GMT

Connected

SDMS>

**The XML protocol**  The XML protocol returns an XML structure as the result from a command.

connect donald identified by 'duck' with protocol = xml;

<OUTPUT>
<Data>
<TITLE>Connect</TITLE>
<RECORD>
<CONNECT_TIME>19 Jan 2005 11:15:16 GMT</CONNECT_TIME></RECORD>
</DATA>
<FEEDBACK>Connected</FEEDBACK>
</OUTPUT>

**The python protocol**  The python protocol returns a Python structure that can be evaluated using the Python eval function.

connect donald identified by 'duck' with protocol = python;

{  
'DATA' :  
{  
'TITLE' : 'Connect',  
'DESC' : [  
'CONNECT_TIME'  
],  
'RECORD' : {  
'CONNECT_TIME' : '19 Jan 2005 11:16:08 GMT'}  
},  
'FEEDBACK' : 'Connected'  
}

**The perl protocol**  The perl protocol returns a Perl structure that can be evaluated using the Perl eval function.

connect donald identified by 'duck' with protocol = perl;

{  
'DATA' =>  
{  
}
Jobserver Commands

`connect`

```php
'TITLE' => 'Connect',
'DESC' => [
    'CONNECT_TIME'
],
'RECORD' => {
    'CONNECT_TIME' => '19 Jan 2005 11:19:19 GMT'
},
'FEEDBACK' => 'Connected'
```

**Output**

*Output*  This statement returns a confirmation of a successful operation
deregister

Purpose

The purpose of the deregister statement is to notify the server that the jobserver is not to process jobs anymore. See also the register statement on page 238.

Syntax

The syntax for the deregister statement is

\[ \text{deregister serverpath . servername} \]

Description

The deregister statement is used to notify the server about a more or less permanent failure of a job server. This message prompts different server actions. Firstly, all the running jobs on the job server (i.e. jobs in the state started, running, to_kill and killed) are set to the state broken_finished. Jobs in the state starting are reset to runnable. The job server is then removed from the list of job servers that are able to process jobs so that this job server is consequently no longer allocated any more jobs. A side effect of this is that jobs that can only run on this server due to their resource requirements are set to the state error with the message "Cannot run in any scope because of resource shortage". Finally, a complete reschedule is executed so that jobs are redistributed among the job servers. The job server is added to the list of job-processing job servers again by re-registering it (refer to the register statement on page 238).

Output

This statement returns a confirmation of a successful operation.
Jobserver Commands

disconnect

disconnect

Purpose

Purpose The purpose of the disconnect statement is to terminate the server connection.

Syntax

Syntax The syntax for the disconnect statement is

disconnect

Description

Description The connection to the server can be shut down using the disconnect statement.

Output

Output This statement returns a confirmation of a successful operation
get next job

Purpose

The purpose of the get next job command is to fetch the next assignment from the server.

Syntax

The syntax for the get next job statement is

get next job

Description

The job server uses the get next job statement to fetch the next command to be executed from the server.

Output

This statement returns an output structure of type table.

Main output description  The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMAND</td>
<td>The command to be executed by the job server. (NOP, ALTER, SHUTDOWN, STARTJOB)</td>
</tr>
<tr>
<td>CONFIG</td>
<td>Changed configuration. This value is only present in the case of an ALTER command.</td>
</tr>
<tr>
<td>ID</td>
<td>The ID of the job to be started; only present for the STARTJOB command.</td>
</tr>
<tr>
<td>DIR</td>
<td>The working directory of the job to be started; only present for the STARTJOB command.</td>
</tr>
<tr>
<td>LOG</td>
<td>The log file of the job to be started; only present for the STARTJOB command.</td>
</tr>
<tr>
<td>LOGAPP</td>
<td>Indicator showing whether the log file is to be opened with Append; only present for the STARTJOB command.</td>
</tr>
</tbody>
</table>

<tr>
<td>ENV</td>
<td>Additional entries for the environment of the executable to be started; only present for the STARTJOB command.</td>
</tr>
<tr>
<td>RUN</td>
<td>Number of the run. Refer also to the alter job statement on page 45; only present for the STARTJOB command.</td>
</tr>
<tr>
<td>JOBENV</td>
<td>Vector of key value pairs defining the job defined environment variables to set before job execution.</td>
</tr>
</tbody>
</table>

Table 27.1.: Description of the output structure of the get next job statement
**multicommand**

**Purpose**

This statement is used to control the behaviour of the SDMS Server.

**Syntax**

The syntax for the multicommand statement is

```
begin multicommand commandlist end multicommand
```

```
begin multicommand commandlist end multicommand rollback
```

**Description**

The multicommands allow multiple SDMS commands to be executed together, i.e. in one transaction. This ensures that either all the statements are executed without any errors or nothing happens at all. Not only that, but the transaction is not interrupted by other write transactions.

If the *rollback* keyword is specified, the transaction is undone at the end of the processing. This means that you can test whether the statements can be correctly processed (technically speaking).

**Output**

This statement returns a confirmation of a successful operation.
Jobserver Commands  reassure

**reassure**

**Purpose**

*Purpose*  The purpose of the reassure job statement is to get a confirmation from the server about the necessity of starting a job after a jobserver was started.

**Syntax**

*Syntax*  The syntax for the reassure statement is

```
reassure jobid [ with run = integer ]
```

**Description**

*Description*  With the reassure statement a job server gets a confirmation from the server as to whether a job should be started. This statement is used when a job server boots up and there is a job in the starting state.

**Output**

*Output*  This statement returns a confirmation of a successful operation
register

Purpose

The purpose of the register statement is to notify the server that the jobserver is ready to process jobs.

Syntax

The syntax for the register statement is

```
register serverpath . servername
with pid = pid [ suspend ]
```

```
register with pid = pid
```

Description

The first form is used by the operator to enable jobs to be executed by the specified job server.
The second form is used by the job server itself to notify the server that it is ready to execute jobs.
Jobs are scheduled for this job server (unless it is suspended) regardless of whether the server is connected or not.
Refer to the deregister statement on page 144.

pid The pid option provides the server with information about the job server’s process ID at operating level.

suspend The suspend option causes the job server to be transferred to a suspended state.

Output

This statement returns a confirmation of a successful operation
Part IV.

Job Commands
28. Job Commands
alter job

Purpose

The purpose of the alter job statement is to change properties of the specified job. This statement is used by job administrators, job servers, and by the job itself.

Syntax

The syntax for the alter job statement is

```
alter job jobid
with WITHITEM {, WITHITEM}
```

```
alter job
with WITHITEM {, WITHITEM}
```

WITHITEM:

```
< suspend | suspend restrict | suspend local | suspend local restrict >
cancel
clear warning
comment = string
error text = string
exec pid = pid
exit code = signed_integer
exit state = statename [ force ]
ext pid = pid
ignore resource = ( id [, id] )
ignore dependency = ( jobid [ recursive ] {, jobid [ recursive ]} )
k ill
nicevalue = signed_integer
priority = integer
renice = signed_integer
rerun [ recursive ]
resume
< noresume | resume in period | resume at datetime >
run = integer
state = JOBSTATE
timestamp = string
warning = string
```

JOBSTATE:

```
The alter job command is used for several purposes. Firstly, job servers use this command to document the progress of a job. All the state transitions a job undergoes during the time when the job is the responsibility of a job server are performed using the alter job command.

Secondly, some changes such as ignoring dependencies or resources, as well as changing the priority of a job, are carried out manually by an administrator. The Exit State of a job in a Pending State can be set by the job itself or by a process that knows the job ID and key of the job that is to be changed.

The cancel option is used to cancel the addressed job and all non-Final Children. A job can only be cancelled if neither the job itself nor one of its children is active. Cancelling a running job will set the job in a cancelling state. The effective cancel is postponed until the job is finished.

If a Scheduling Entity is dependent upon the cancelled job, it can become unreachable. In this case the dependent job does not acquire the Unreachable Exit State defined in the Exit State Profiles, but is set as having the Job State “Unreachable”. It is the operator’s task to restore this job back to the job state “Dependency Wait” by ignoring dependencies or even to cancel it.

Cancelled jobs are considered to be just like Final Jobs without a Final Exit. This means that the parents of a cancelled job become final without taking into consideration the Exit State of the cancelled job. In this case the dependent jobs of the parents continue running normally.

The cancel option can only be used by users.

The comment option is used to document an action or to add a comment to the job. Comments can have a maximum length of 1024 characters. Any number of comments can be saved for a job.

Some comments are saved automatically. For example, if a job attains a Restartable State, a log is written to document this fact.
error text  The error text option is used to write error information about a job. This can be done by the responsible job server or a user. The server can write this text itself as well. This option is normally used if the job server cannot start the corresponding process. Possible cases are where it is not possible to switch to the defined working directory, if the executable program cannot be found, or when opening the error log file triggers an error.

exec pid  The exec pid option is used exclusively by the job server to set the process ID of the control process within the server.

exit code  The exit code option is used by the job server to tell the repository server with which Exit Code the process has finished. The repository server now calculates the matching Exit State from the Exit State Mapping that was used.

exit state  The exit state option is used by jobs in a pending state to set their state to another value. This is usually a Restartable or Final State. Alternatively, this option can be used by administrators to set the state of a non-final job. If the Force Flag is not being used, the only states that can be set are those which are theoretically attainable by applying the Exit State Mapping to any Exit Code. The set state must exist in the Exit State Profile.

ext pid  The ext pid option is used exclusively by the job server to set the process ID of the started user process.

ignore resource  The ignore resource option is used to revoke individual Resource Requests. The ignored resource is then no longer requested. If the parameters of a resource are being referenced, that resource cannot be ignored. If invalid IDs have been specified, it is skipped. All other specified resources are ignored. Invalid IDs in this context are the IDs of resources that are not requested by the job. The ignoring of resources is logged.

ignore dependency  The ignore dependency option is used to ignore defined dependencies. If the recursive flag is used, not only do the job or batch ignore the dependencies, but its children do so as well.

kill  The kill option is used to submit the defined Kill Job. If no Kill Job has been defined, it is not possible to forcibly terminate the job from within BICsuite. The job obviously has to be active, that means it must be running, killed or broken_active.
The last two states are not regular cases. When a Kill Job has been submitted, the Job State is to_kill. After the Kill Job has terminated, the Job State of the killed job is set to killed unless it has been completed, in which case it is finished or final. This means that the job with the Job State killed is always still running and that at least one attempt has been made to terminate it.

**nicevalue**  The nicevalue option is used to change the priority or the nicevalue of a job or batch and all of its children. If a child has several parents, any changes you make can, but do not necessarily have to, affect the priority of the child in the nicevalue of one of the parents. Where there are several parents, the maximum nicevalue is searched for.

This means that if Job C has three Parents P1, P2 and P3, whereby P1 sets a nice value of 0, P2 sets a nicevalue of 10 and P3 a nicevalue of -10, the effective nicevalue is -10. (The lower the nicevalue the better). If the nicevalue for P2 is changed to -5, nothing happens because the -10 of P3 is better than -5. If the nicevalue of P3 falls to 0, the new effective nicevalue for Job C is -5.

The nicevalues can have values between -100 and 100. Values that exceed this range are tacitly adjusted.

**priority**  The priority option is used to change the (static) priority of a job. Because batches and milestones are not executed, priorities are irrelevant to them.

Changing the priority only affects the changed job. Valid values lie between 0 and 100. In this case, 100 corresponds to the lowest priority and 0 is the highest priority.

When calculating the dynamic priority of a job, the scheduler begins with the static priority and adjusts it according to how long the job has already been waiting. If more than one job has the same dynamic priority, the job with the lowest job ID is scheduled first.

**renice**  The renice option is similar to the nicevalue option with the difference that the renice option functions relatively while the nicevalue option functions absolutely. If some batches have a nicevalue of 10, a renice of -5 causes the nicevalue to rise to 5. (It rises because the lower the number, the higher the priority).

**rerun**  The rerun option is used to restart a job in a Restartable State. If you attempt to restart a job that is not restartable, an error message is displayed. A job is restartable if it is in a Restartable State or it has the Job State error or broken_finished.

If the recursive flag has been specified, the job itself and all its direct and indirect children that are in a Restartable State are restarted. If the job itself is final, this is not considered to be an error. It is therefore possible to recursively restart batches.
The resume option is used to reactivate a suspended job or batch. There are two ways to do this. The suspended job or batch can either be reactivated immediately or a delay can be set. A delay can be achieved by specifying either the number of time units for the delay or the time when the job or batch is to be activated. For details about specifying a time, refer to the overview on page 6. The resume option can be used together with the suspend option. Here, the job is suspended and then resumed again after (or at) a specified time.

The run option is used by the job server to ensure that the modified job matches the current version. Theoretically, the computer could crash after a job has been started by a job server. To complete the work, the job is manually restarted from another job server. After the first system has been booted, the job server can attempt to change the job state to broken_finished without knowing anything about what happened after the crash. Using the run option then prevents the wrong state from being set.

The state option is mainly used by job servers, but it can also be used by administrators. It is not recommended to do so unless you know exactly what you are doing. The usual procedure is that the job server sets the state of a job from starting to started, from started to running, and from running to finished. In the event of a crash or any other problems, it is possible for the job server to set the job state to broken_active or broken_finished. This means that the Exit Code of the process is not available and the Exit State has to be set manually.

The suspend option is used to suspend a batch or job. It always functions recursively. If a parent is suspended, its children are all suspended as well. The resume option is used to reverse the situation. The effect of the restrict option is that cwa resume can be done by members of the group ADMIN only.

The timestamp option is used by the job server to set the timestamps of the state transition in keeping with the local time from the perspective of job server.

Output

This statement returns a confirmation of a successful operation
connect

Purpose

The purpose of the connect statement is to authenticate a job to the server.

Syntax

The syntax for the connect statement is

```
connect job jobid identified by string [with WITHITEM {, WITHITEM} ]
```

WITHITEM:

- **command** = ( sdms-command )
- **protocol** = PROTOCOL
- **session** = string
- **timeout** = integer
- < trace | notrace >
- **trace level** = integer

PROTOCOL:

- json
- line
- perl
- python
- serial
- xml

Description

The connect command is used to authenticate the connected process on the server to. A communication protocol can be optionally specified. The default protocol is line.

The selected protocol defines the output format. All protocols except for serial return ASCII output. The protocol serial returns a serialized Java object.

An executable command can also be returned when the connection is established. In this case, the output of the accompanying command is used as the output for the connect command. If the command fails, but the connect was successful, the connection remains active.

An example for all protocols except the serial protocol is given below.
The line protocol  The line protocol only returns an ASCII text as the result from a command.

connect donald identified by 'duck' with protocol = line;

Connect

CONNECT_TIME : 19 Jan 2005 11:12:43 GMT

Connected

SDMS>

The XML protocol  The XML protocol returns an XML structure as the result from a command.

connect donald identified by 'duck' with protocol = xml;

<OUTPUT>
<Data>
<TITLE>Connect</TITLE>
<RECORD>
<CONNECT_TIME>19 Jan 2005 11:15:16 GMT</CONNECT_TIME></RECORD>
</Data>
<FEEDBACK>Connected</FEEDBACK>
</OUTPUT>

The python protocol  The python protocol returns a Python structure that can be evaluated using the Python eval function.

connect donald identified by 'duck' with protocol = python;

{ 'DATA' :

 'TITLE' : 'Connect',
 'DESC' : [
 'CONNECT_TIME'
 ],
 'RECORD' : [
 'CONNECT_TIME' : '19 Jan 2005 11:16:08 GMT'
 ]
 , 'FEEDBACK' : 'Connected'
}

The perl protocol  The perl protocol returns a Perl structure that can be evaluated using the Perl eval function.

connect donald identified by 'duck' with protocol = perl;

{ 'DATA' =>

}
connect Job Commands

'TITLE' => 'Connect',
'DESC' => ['CONNECT_TIME'],
'RECORD' => {'CONNECT_TIME' => '19 Jan 2005 11:19:19 GMT'},
'FEEDBACK' => 'Connected'}

Output

This statement returns a confirmation of a successful operation

Output
disconnect

Purpose

Purpose  The purpose of the disconnect statement is to terminate the server connection.

Syntax

Syntax  The syntax for the disconnect statement is

    disconnect

Description

Description  The connection to the server can be shut down using the disconnect statement.

Output

Output  This statement returns a confirmation of a successful operation
**get parameter**

**Purpose**

The purpose of the get parameter statement is to get the value of the specified parameter within the context of the requesting job, respectively the specified job.

**Syntax**

The syntax for the get parameter statement is

```
get parameter parametername [ < strict | warn | liberal > ]
```

```
get parameter of jobid parametername [ < strict | warn | liberal > ]
```

**Description**

The get parameter statement is used to get the value of the specified parameter within the context of a job.

The additional option has the following meaning:

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>strict</td>
<td>The server returns an error if the requested parameter is not explicitly declared in the job definition.</td>
</tr>
<tr>
<td>warn</td>
<td>A message is written to the server’s log file when an attempt is made to determine the value of an undeclared parameter.</td>
</tr>
<tr>
<td>liberal</td>
<td>An attempt to query an undeclared parameter is tacitly allowed. The default behaviour depends on the configuration of the server.</td>
</tr>
</tbody>
</table>

**Output**

This statement returns an output structure of type record.

**Main output description** The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE</td>
<td>Value of the requested parameter</td>
</tr>
</tbody>
</table>

Table 28.1.: Description of the output structure of the get parameter statement
get submittag

Purpose

The purpose of the get submittag statement is to get a (server local) unique identifier from the server. This identifier can be used to avoid race conditions between frontend and backend when submitting jobs.

Syntax

The syntax for the get submittag statement is

```
get submittag
```

Description

The get submittag statement is used to acquire an identification from the server. This prevents race conditions between the front end and back end when jobs are submitted.

Such a situation arises when feedback about the submit does not reach the front end due to an error. By using a submittag, the front end can safely start a second attempt. The server recognises whether the job in question has already been submitted and responds accordingly. This reliably prevents the job from being submitted twice.

Output

This statement returns an output structure of type record.

Table 28.2.: Description of the output structure of the get submittag statement
multicommand

Purpose
This statement is used to control the behaviour of the SDMS Server.

Syntax
The syntax for the multicommand statement is

```
begin multicommand commandlist end multicommand
```

Description
The multicommands allow multiple SDMS commands to be executed together, i.e. in one transaction. This ensures that either all the statements are executed without any errors or nothing happens at all. Not only that, but the transaction is not interrupted by other write transactions.

If the `rollback` keyword is specified, the transaction is undone at the end of the processing. This means that you can test whether the statements can be correctly processed (technically speaking).

Output
This statement returns a confirmation of a successful operation
**set parameter**

**Purpose**

*Purpose*  The purpose of the set parameter statement is to set the value of the specified parameters within the context of the requesting job, respectively the specified job.

**Syntax**

*Syntax*  The syntax for the set parameter statement is

```
set parameter parametername = string {, parametername = string}
```

```
set parameter < on | of > jobid parametername = string {, parametername = string}
```

```
set parameter < on | of > jobid parametername = string {, parametername = string} identified by string
```

**Description**

*Description*  The set parameter statements can be used to set jobs or user parameter values in the context of the job.

If the *identified by* option is specified, the parameter is only set if the pair *jobid* and *string* would allow a logon.

**Output**

*Output*  This statement returns a confirmation of a successful operation
set state

Purpose

The purpose of the set state statement is to set the exit state of a job in a pending exit state.

Syntax

The syntax for the set state statement is

\[ \text{set state} = \text{statename} \]

Description

The set state statement is used to set the Exit State of a job to a Pending Exit State.

Output

This statement returns a confirmation of a successful operation
submit

Purpose

Purpose
The purpose of the submit statement is to execute a master batch or job as well as all defined children.

Syntax

Syntax
The syntax for the submit statement is

```
submit folderpath [ with WITHITEM {, WITHITEM} ]

submit aliasname [ with WITHITEM {, WITHITEM} ]
```

WITHITEM:

```
  check only
  | childdtag = string
  | nicevalue = signed_integer
  | parameter = none
  | parameter = ( PARAM {, PARAM} )
  | < noresume | resume in period | resume at datetime >
  | submittag = string
  | < nosuspend | suspend >
  | unresolved = < error | ignore | suspend | defer >
  | group = groupname
```

PARAM:

```
  parametername = < string | number >
```

Description

Description
The submit statement is used to submit a job or batch. There are two kinds of submit command:

- The first kind is used by users, who can also be programs, and the Time Scheduling Module. This form submits Master Jobs and Batches.
- The second form of the statement is used by jobs to submit dynamic children.
check only  The check only option is used to verify whether a Master Submittable Batch or Job can be submitted. This means that a check is run to ascertain whether all the dependencies can be fulfilled and all the referenced parameters are defined. Whether the jobs can be executed in any scope or not is not verified. This is a situation that can arise at any point during the runtime.
Positive feedback means that, from the system’s perspective, the job or batch can be submitted.

childtag  The childtag option is used by jobs to submit several instances of the same Scheduling Entity and to be able to differentiate between them.
An error is triggered if the same Scheduling Entity is submitted twice using the same childtag. The content of the childtag has no further significance for the Scheduling System.
The maximum length for a childtag is 70 characters. The childtag option is ignored in the case of a Master Submit.

group  The group option is used to set the owner group to the specified value. The user must belong to this group unless he belongs to the ADMIN privileged group. In this case, any group can be specified.

nicevalue  The nicevalue option defines a correction that is used for the calculation of the priorities for the job and its children. Values between -100 and 100 are permitted.

parameter  The parameter option is used to specify the value of Job Parameters for the submit. The parameters are set in the scope of the Master Batch or Job. This means that if parameters are specified that are not defined in the Master Batch or Job, these parameters are invisible to any children.

submittag  If the submittag is specified, it must have a unique name for the Submitted Entity. This tag was introduced to be able to programmatically submit jobs and batches and to resubmit the job or batch with the same tag following a crash of one of the components. If the job submit was successful the first time, the second submit will report an error. If not, the second submit will succeed.

unresolved  The unresolved option defines how the server is to react to unresolved dependencies. This option is mainly used if parts of a batch are submitted following repair work. The faulty part is normally cancelled and then resubmitted as a Master Run. In this case the previous dependencies have to be ignored otherwise the submit will fail.
Job Commands

submit

**suspend** The suspend option is used to submit jobs or batches and to suspend them at the same time. If nothing is defined, they are not suspended. This can be explicitly specified at the submit time.
If a job or batch was suspended, neither it nor its children are started. If a job is already running, it will not reach a Final State if it is suspended.

**resume** The resume option can be used together with the suspend option to cause a delayed execution. There are two ways to do this. A delay can be achieved by specifying either the number of time units for the delay the time when the job or batch is to be activated.
This option can be used to reproduce the `at` functionality without creating a schedule.

**Output**

*Output* This statement returns an output structure of type record.

**Main output description** The data items of the output are described in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>ID of the Submitted Entity.</td>
</tr>
</tbody>
</table>
